LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National Semiconductor Corporation 2900 Semiconductor Drive, P.O. Box 58090, Santa Clara, California 95052-8090 1-800-272-9959 TWX (910) 339-9240

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied, and National reserves the right, at any time without notice, to change said circuitry or specifications.

LV8571A Low Voltage Timer Clock Peripheral (TCP)

General Description

The LV8571A is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports. The address space is organized as 2 software selectable pages of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, the Timers and their data RAM, and the Time Save RAM. Any of the RAM locations that are not being used for their intended purpose may be used as general purpose CMOS RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week, day of month and day of year counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the crystal and two capacitors. The choice of crystal frequency is program selectable.

Two independent multifunction 10 MHz 16-bit timers are provided. These timers operate in four modes. Each has its own prescaler and can select any of 7 possible clock inputs. Thus, by programming the input clocks and the timer counter values a very wide range of timing durations can be achieved. The range is from about 400 ns (4.915 MHz oscillator) to 65,535 seconds (18 hrs., 12 min.).

Power failure logic and control functions have been integrated on chip. This logic is used by the TCP to issue a power fail

interrupt, and lock out the μP interface. The time power fails may be logged into RAM automatically when $V_{BB} > V_{CC}$. Additionally, two supply pins are provided. When $V_{BB} > V_{CC}$, internal circuitry will automatically switch from the main supply to the battery supply. Status bits are provided to indicate initial application of battery power, system power, and low battery detect. (Continued)

Features

- 3.3V $\pm 10\%$ supply
- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week and day of years counters
 - Four selectable oscillator frequencies
 - Parallel resonant oscillator
- Two 16-bit timers
 - 10 MHz external clock frequency
 - Programmable multi-function output
 - Flexible re-trigger facilities
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, timer and power fail interrupts
- Up to 44 bytes of CMOS RAM
- INTR/MFO pins programmable High/Low and push-pull or open drain

Block Diagram

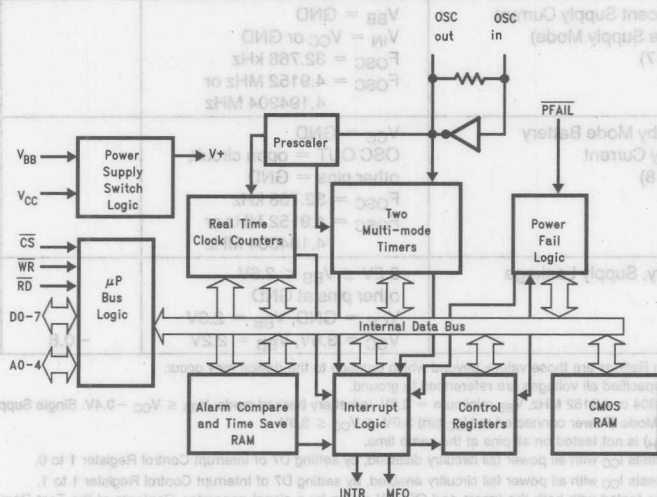

FIGURE 1

TL/F/11416-1

Absolute Maximum Ratings (Notes 1 & 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	-0.5V to +7.0V
DC Input Voltage (V_{IN})	-0.5V to $V_{CC} + 0.5V$
DC Output Voltage (V_{OUT})	-0.5V to $V_{CC} + 0.5V$
Storage Temperature Range	-65°C to +150°C
Power Dissipation (PD)	500 mW
Lead Temperature (Soldering, 10 sec.)	260°C

DC Electrical Characteristics

$V_{CC} = 3.3V \pm 10\%$, $V_{BB} = 2.5V$, $V_{PFAIL} > V_{IH}$, $C_L = 100$ pF (unless otherwise specified)

Symbol	Parameter	Conditions	Min	Max	Units
V_{IH}	High Level Input Voltage (Note 4)	Any Inputs Except OSC IN, OSC IN with External Clock	2.0 $V_{BB} - 0.2$	$V_{CC} + 0.3$	V
V_{IL}	Low Level Input Voltage	All Inputs Except OSC IN, OSC IN with External Clock	-0.3 -0.3	0.8 0.2	V
V_{OH}	High Level Output Voltage (Excluding OSC OUT)	$I_{OUT} = -20 \mu A$ $I_{OUT} = -2.0$ mA	$V_{CC} - 0.2$ 2.4		V
V_{OL}	Low Level Output Voltage (Excluding OSC OUT)	$I_{OUT} = 20 \mu A$ $I_{OUT} = 2.0$ mA		0.2 0.3	V
I_{IN}	Input Current (Except OSC IN)	$V_{IN} = V_{CC}$ or GND		± 0.7	μA
I_{OZ}	Output TRI-STATE® Current	$V_{OUT} = V_{CC}$ or GND		± 1	μA
I_{LKG}	Output High Leakage Current MFO, INTR Pins	$V_{OUT} = V_{CC}$ or GND Outputs Open Drain		± 1	μA
I_{CC}	Quiescent Supply Current (Note 7)	$F_{OSC} = 32.768$ kHz $V_{IN} = V_{CC}$ or GND (Note 5) $V_{IN} = V_{CC}$ or GND (Note 6) $V_{IN} = V_{IH}$ or V_{IL} (Note 6)		220 700 8	μA μA mA
		$F_{OSC} = 4.194304$ MHz or 4.9152 MHz $V_{IN} = V_{CC}$ or GND (Note 6) $V_{IN} = V_{IH}$ or V_{IL} (Note 6)		6 8	mA
I_{CC}	Quiescent Supply Current (Single Supply Mode) (Note 7)	$V_{BB} = GND$ $V_{IN} = V_{CC}$ or GND $F_{OSC} = 32.768$ kHz $F_{OSC} = 4.9152$ MHz or 4.194304 MHz		60 6	μA mA
I_{BB}	Standby Mode Battery Supply Current (Note 8)	$V_{CC} = GND$ OSC OUT = open circuit, other pins = GND $F_{OSC} = 32.768$ kHz $F_{OSC} = 4.9152$ MHz or 4.194304 MHz		8 400	μA μA
I_{BLK}	Battery, Supply Leakage	$2.2V \leq V_{BB} \leq 2.6V$ other pins at GND $V_{CC} = GND$, $V_{BB} = 2.6V$ $V_{CC} = 3.6V$, $V_{BB} = 2.2V$	-0.8	0.8	μA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: For $F_{OSC} = 4.194304$ or 4.9152 MHz, V_{BB} minimum = 2.8V. In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$. Single Supply Mode: Data retention voltage is 2.2V min. In single Supply Mode (Power connected to V_{CC} pin) $3.0V \leq V_{CC} \leq 3.6V$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: This specification is tested with both the timers and OSC IN driven by a signal generator. Contents of the Test Register = 00(H), the MFO pin is not configured as buffered oscillator out and MFO, INTR, are configured as open drain.

Note 8: This specification is tested with both the timers off, and only OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

Operation Conditions

	Min	Max	Unit
Supply Voltage (V_{CC}) (Note 3)	3.0	3.6	V
Supply Voltage (V_{BB}) (Note 3)	2.2	$V_{CC} - 0.4$	V
DC Input or Output Voltage (V_{IN} , V_{OUT})	0.0	V_{CC}	V
Operation Temperature (T_A)	-40	+85	°C
Electro-Static Discharge Rating		1	kV
Typical Values			
θ_{JA} DIP		Board	59°C/W
		Socket	65°C/W
θ_{JA} PLCC		Board	77°C/W
		Socket	85°C/W

AC Electrical Characteristics

$V_{CC} = 3.3V \pm 10\%$, $V_{BB} = 2.5V$, $V_{PFAIL} > V_{IH}$, $C_L = 100 \text{ pF}$ (unless otherwise specified)

Symbol	Parameter	Min	Max	Units
READ TIMING				
t_{AR}	Address Valid Prior to Read Strobe	10		ns
t_{RW}	Read Strobe Width (Note 9)	100		ns
t_{CD}	Chip Select to Data Valid Time		100	ns
t_{RAH}	Address Hold after Read (Note 10)	2		ns
t_{RD}	Read Strobe to Valid Data		90	ns
t_{DZ}	Read or Chip Select to TRI-STATE		80	ns
t_{RCH}	Chip Select Hold after Read Strobe (Note 10)	0		ns
t_{DS}	Minimum Inactive Time between Read or Write Accesses	70		ns

WRITE TIMING				
t_{AW}	Address Valid before Write Strobe	10		ns
t_{WAH}	Address Hold after Write Strobe (Note 10)	2		ns
t_{CW}	Chip Select to End of Write Strobe	110		ns
t_{WW}	Write Strobe Width (Note 11)	100		ns
t_{DW}	Data Valid to End of Write Strobe	70		ns
t_{WDH}	Data Hold after Write Strobe (Note 10)	2		ns
t_{WCH}	Chip Select Hold after Write Strobe (Note 10)	0		ns

INTERRUPT TIMING				
t_{ROLL}	Clock rollover to INTR out is typically 20 μs			

Note 9: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 10: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 11: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output Reference Levels	1.3V
TRI-STATE Reference Levels (Note 13)	Active High +0.5V Active Low –0.5V

Note 12: $C_L = 100 \text{ pF}$, includes jig and scope capacitance.

Note 13: $S_1 = V_{CC}$ for active low to high impedance measurements.

$S_1 = \text{GND}$ for active high to high impedance measurements.

$S_1 = \text{open}$ for all other timing measurements.

Capacitance ($T_A = 25^\circ\text{C}$, $f = 1 \text{ MHz}$)

Symbol	Parameter (Note 14)	Typ	Units
C_{IN}	Input Capacitance	5	pF
C_{OUT}	Output Capacitance	7	pF

Note 14: This parameter is not 100% tested.

Note 15: Output rise and fall times 25 ns max (10%–90%) with 100 pF load.

TL/F/11416–2

Timing Waveforms

Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

One dedicated general purpose interrupt output is provided. A second interrupt output is available on the Multiple Function Output (MFO) pin. Each of these may be selected to generate an interrupt from any source. Additionally, the MFO pin may be programmed to be either as oscillator output or Timer 0's output.

Pin Description

CS, RD, WR (Inputs): These pins interface to μP control lines. The CS pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the TCP. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} , and the correct crystal select bits in the Real Time Mode Register have been set.

MFO (Output): The multi-function output can be used as a second interrupt output for interrupting the μP . This pin can also provide an output for the oscillator or the internal Timer 0. The MFO output can be programmed active high or low, open drain or push-pull. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . This pin is configured open drain during battery operation ($V_{BB} > V_{CC}$).

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The INTR output can be programmed active high or low, push-pull or open drain. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . This pin is configured open drain during battery operation ($V_{BB} > V_{CC}$).

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μP 's data bus and are used to read from and write to the TCP. When the PFAIL pin goes low and a write is not in progress, these pins are at TRI-STATE.

mode, in a minimum of 30 μs or a maximum of 63 μs unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

V_{BB} (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be used then this pin must be tied to ground, the TCP programmed for single power supply only, and power applied to the V_{CC} pin.

V_{CC} : This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

See NS Package Number N24C

FIGURE 2 LV8571A Internal Memory Map

Functional Description

The LV8571A contains a fast access real time clock, two 10 MHz, 16-bit timers, interrupt control logic, power fail detect logic, and CMOS RAM. All functions of the TCP are controlled by a set of nine registers. A simplified block diagram that shows the major functional blocks is given in Figure 1.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management
6. Timers

FIGURE 2. LV8571A Internal Memory Map

TL/F/11416-6

Functional Description (Continued)

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of 1 M Ω . The user should be aware that the control registers will contain random data. The first task to be carried out in an initialization routine is to start the oscillator by writing to the crystal select bits in the Real Time Mode Register. If the LV8571A is configured for single supply mode, an extra 50 μ A may be consumed until the crystal select bits are programmed. The user should also ensure that the TCP is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 10 bytes of counters, which count from 1/100 of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, day of year, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Also note that the day of year counter is 12 bits long and occupies two addresses. Upon initial application of power the counters will contain random information.

READING THE CLOCK: VALIDATED READ

Since clocking of the counter occurs asynchronously to reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time

Save Enable bit (D7) of the Interrupt Routing Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the TCP or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

The above method is useful when the entire clock is being corrected. If one location is being updated the clock need not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the 1/100 of a second periodic interrupt. Then wait an additional 16 μ s, and then write the data to the clock.

PRESCALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3). The crystal frequency that can be selected are: 32 kHz, 32.768 kHz, 4.9152 MHz, and 4.194304 MHz.

Once 32 kHz is generated it feeds both timers and the clock. The clock and timer prescalers can be independently enabled by controlling the timer or clock Start/Stop bits.

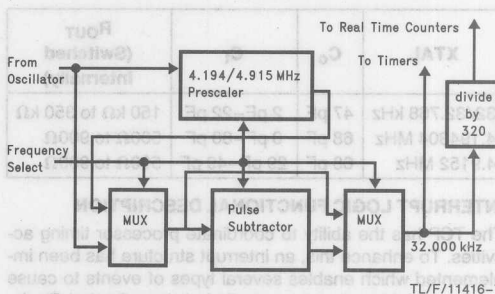

FIGURE 3. Programmable Clock Prescaler Block

Functional Description (Continued)

The oscillator is programmed via the Real Time Mode Register to operate at various frequencies. The crystal oscillator is designed to offer optimum performance at each frequency. Thus, at 32.768 kHz the oscillator is configured as a low frequency and low power oscillator. At the higher frequencies the oscillator inverter is reconfigured. In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the **load capacitance** specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

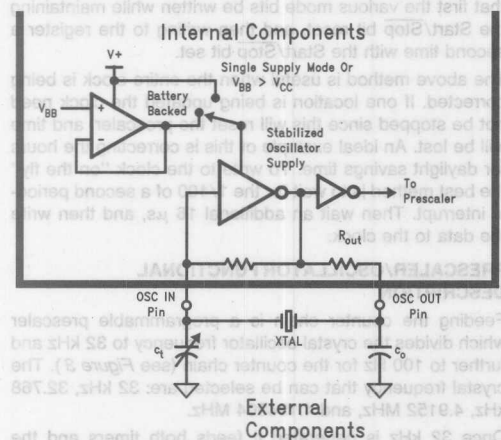

FIGURE 4. Oscillator Circuit Diagram

XTAL	C ₀	C _t	R _{OUT} (Switched Internally)
32/32.768 kHz	47 pF	2 pF–22 pF	150 kΩ to 350 kΩ
4.194304 MHz	68 pF	0 pF–80 pF	500Ω to 900Ω
4.9152 MHz	68 pF	29 pF–49 pF	500Ω to 900Ω

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The TCP has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and also Figure 5 and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1. Any of the interrupts can be routed to either the INTR pin or the MFO pin, depending on how the Interrupt Routing register is programmed. This, for example, enables the user to dedicate the MFO as a non-maskable interrupt pin to the CPU for power failure detection and enable all other interrupts to appear on the INTR pin. The polarity for the active interrupt can be programmed in the Output Mode Register for either active high or low, and open drain or push pull outputs.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Page Select	Address
Main Status Register	X	X	00H
Periodic Flag Register	0	0	03H
Interrupt Routing Register	0	0	04H
Interrupt Control Register 0	1	0	03H
Interrupt Control Register 1	1	0	04H
Output Mode Register	1	0	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all TCP interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the TCP to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system.

Note that the Interrupt Status Flag will only monitor the state of the MFO output if it has been configured as an interrupt output (see Output Mode Register description). This is true, regardless of the state of the Interrupt Routing Register. Thus the Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.

Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1–D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm or Timer interrupts that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the appropriate Alarm or Timer interrupt enable bits are set (see Figure 5).

Disabling the periodic bits will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see Figure 5).

To clear a flag in bits D2–D5 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Functional Description (Continued)

Interrupts Fall Into Four Categories:

1. The Timer Interrupts: For description see Timer Section.
2. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
3. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.
4. The Power Fail Interrupt: Issued upon recognition of a power fail condition by the internal sensing logic. The power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The TCP then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 03 (BCD), the minutes compare with 15 (BCD) and the faster counters with 00 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see Figure 5. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

Functional Description (Continued)

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register. The Periodic Route bit in the Interrupt Routing Register is used to route the periodic interrupt events to either the INTR output or the MFO output.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μ P clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μ P, but it cannot be cleared; it is cleared automatically by the TCP when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set.

The Power Fail Route bit determines which output the interrupt will appear on. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the LV8571A provides circuitry to simplify design in battery backed systems. This circuitry switches over to the back up supply, and isolates the LV8571A from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when PFAIL is low. Debounce logic provides a 30 μ s–63 μ s debounce time, which will prevent noise on the PFAIL pin from being interpreted as a system failure. After 30 μ s–63 μ s the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

Functional Description (Continued)

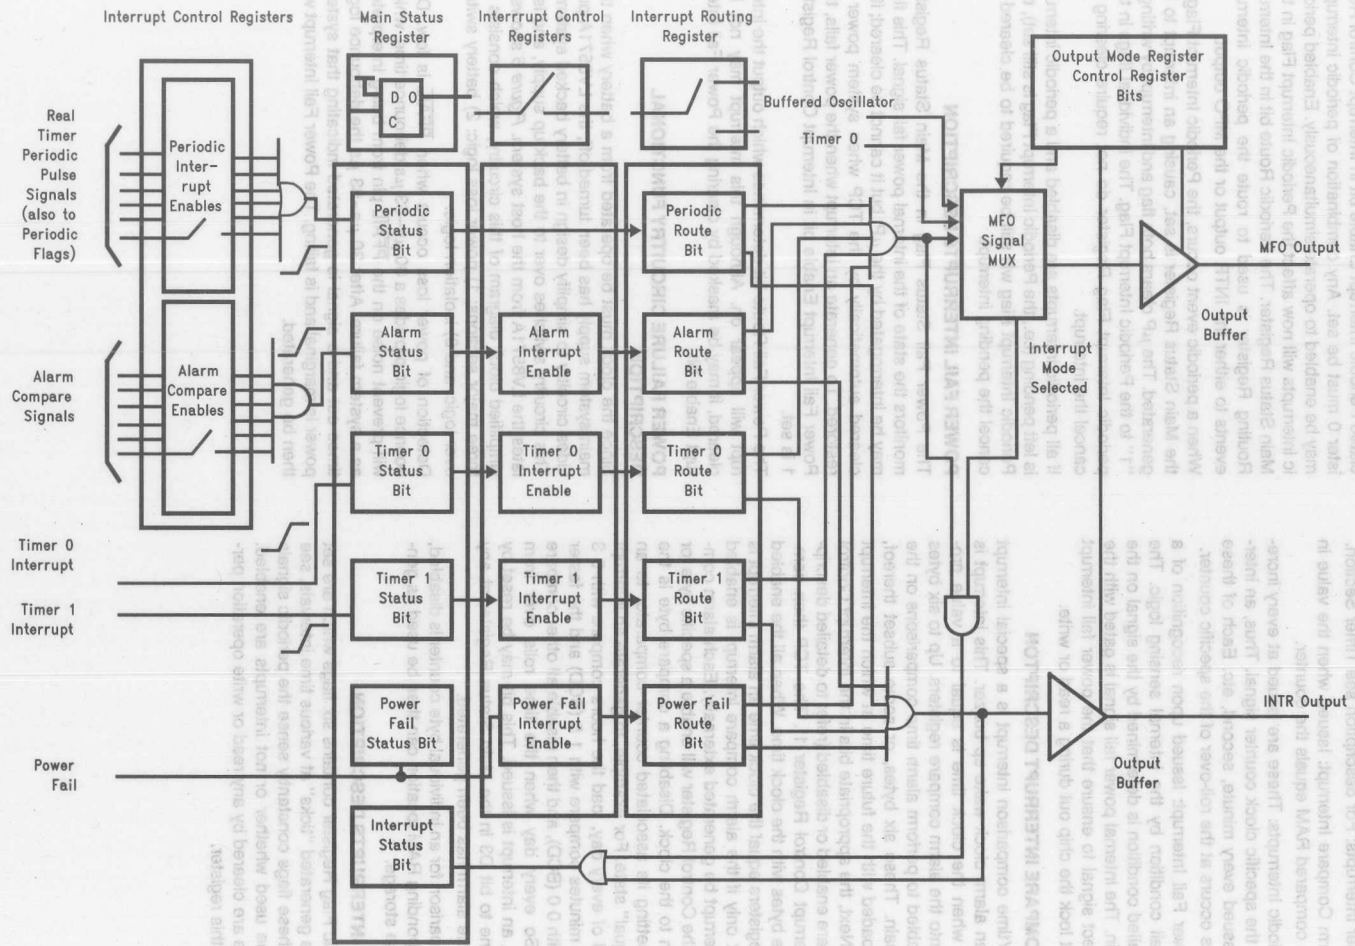

FIGURE 5. Interrupt Control Logic Overview

TL/F/11416-9

Functional Description (Continued)

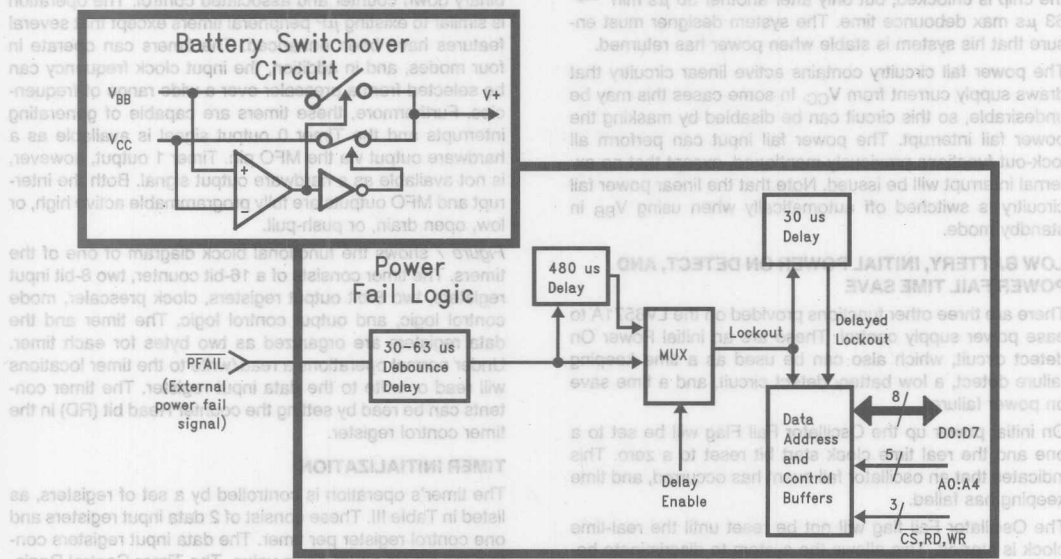

FIGURE 6. System-Battery Switchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

The user may choose to have this power failed signal lock-out the TCP's data bus within 30 μ s min/63 μ s max or to delay the lock-out to enable μ P access after power failure is detected. This delay is enabled by setting the delay enable bit in the Routing Register. Also, if the lock-out delay was not enabled the TCP will disconnect itself from the bus within 30 μ s min \rightarrow 63 μ s max. If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than 30 μ s after the power fail signal is asserted, the lock-out will be forced. If a lock-out delay is enabled, the LV8571A will remain active for 480 μ s after power fail is detected. This will enable the μ P to perform last minute bookkeeping before total system collapse. When the host CPU is finished accessing the TCP it may force the bus lock-out before 480 μ s has elapsed by resetting the delay enable bit.

The battery switch over circuitry is completely independent of the PFAIL pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the TCP will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the TCP will be configured as shown in Table II. Outputs that have a pull-up resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	PFAIL = Logic 0	Standby Mode $V_{BB} > V_{CC}$
CS, RD, WR	Locked Out	Locked Out
A0-A4	Locked Out	Locked Out
D0-D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
PFAIL	Not Isolated	Not Isolated
INTR, MFO	Not Isolated	Open Drain

The Timer and Interrupt Power Fail Operation bits in the Real-Time Mode Register determine whether or not the timers and interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as PFAIL = 0. When PFAIL = 1

Functional Description (Continued)

the chip is unlocked, but only after another 30 μ s min \rightarrow 63 μ s max debounce time. The system designer must ensure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no external interrupt will be issued. Note that the linear power fail circuitry is switched off automatically when using V_{BB} in standby mode.

LOW BATTERY, INITIAL POWER ON DETECT, AND POWER FAIL TIME SAVE

There are three other functions provided on the LV8571A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, a low battery detect circuit, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

Another status bit is the low battery detect. This bit is set only when the clock is operating under the V_{CC} pin, and when the battery voltage is determined to be less than 2.1V (typical). When the power fail interrupt enable bit is low, it disables the power fail circuit and will also shut off the low battery voltage detection circuit as well.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the \overline{PF} pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The LV8571A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC} and \overline{PF} pins. The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits. Until the crystal select bits are initialized, the LV8571A may consume about 50 μ A due to arbitrary oscillator selection at power on.

(This extra 50 μ A is not consumed if the battery backed mode is selected).

TIMER FUNCTIONAL DESCRIPTION

The LV8571A contains 2 independent multi-mode timers. Each timer is composed of a 16-bit negative edge triggered

binary down counter and associated control. The operation is similar to existing μ P peripheral timers except that several features have been enhanced. The timers can operate in four modes, and in addition, the input clock frequency can be selected from a prescaler over a wide range of frequencies. Furthermore, these timers are capable of generating interrupts and the Timer 0 output signal is available as a hardware output via the MFO pin. Timer 1 output, however, is not available as a hardware output signal. Both the interrupt and MFO outputs are fully programmable active high, or low, open drain, or push-pull.

Figure 7 shows the functional block diagram of one of the timers. The timer consists of a 16-bit counter, two 8-bit input registers, two 8-bit output registers, clock prescaler, mode control logic, and output control logic. The timer and the data registers are organized as two bytes for each timer. Under normal operations a read/write to the timer locations will read or write to the data input register. The timer contents can be read by setting the counter Read bit (RD) in the timer control register.

TIMER INITIALIZATION

The timer's operation is controlled by a set of registers, as listed in Table III. These consist of 2 data input registers and one control register per timer. The data input registers contain the timers count down value. The Timer Control Register is used to set up the mode of operation and the input clock rate. The timer related interrupts can be controlled by programming the Interrupt Routing Register and Interrupt Control Register 0. The timer outputs are configured by the Output Mode Register.

TABLE III. Timer Associated Registers

Register Name	Register Select	Page Select	Address
Timer 0 Data MSB	X	0	10H
Timer 0 Data LSB	X	0	0FH
Timer 0 Control Register	0	0	01H
Timer 1 Data MSB	X	0	12H
Timer 1 Data LSB	X	0	11H
Timer 1 Control Register	0	0	02H
Interrupt Routing Register	0	0	04H
Interrupt Control Reg. 0	1	0	03H
Output Mode Register	1	0	02H

All these registers must be initialized prior to starting the timer(s). The Timer Control Register should first be set to select the timer mode with the timer start/stop bit reset. Then when the timer is to be started the control register should be rewritten identically but with the start/stop bit set.

TIMER OPERATION

Each timer is capable of operation in one of four modes. As mentioned, these modes are programmed in each timer's Control Register which is described later. All four modes operate in a similar manner. They operate on the two 8-bit data words stored into the Data Input Register. At the beginning of a counting cycle the 2 bytes are loaded into the timer and the timer commences counting down towards zero. The exact action taken when zero is reached depends on the mode selected, but in general, the timer output will change state, and an interrupt will be generated if the timer interrupts are unmasked.

Functional Description (Continued)

INPUT CLOCK SELECTION

The input frequency to the timers may be selected. Each timer has a prescaler that gives a wide selection of clocking rates. Table IV shows the range of programmable clocks available and the corresponding setting in the Timer Control Register. Note that the output of Timer 1 may be used as the input to Timer 0. This is a cascade option for the timers and allows them to be clocked as a 32-bit down counter.

TABLE IV. Programmable Timer Input Clocks

C2	C1	C0	Selected Clock
0	0	0	Timer 1 Output
0	0	1	Crystal Oscillator
0	1	0	(Crystal Oscillator)/4
0	1	1	93.5 μ s (10.7 kHz)
1	0	0	1 ms (1 kHz)
1	0	1	10 ms (100 Hz)
1	1	0	1/10 Second (10 Hz)
1	1	1	1 Second (1 Hz)

Note that the second and third selections are not fixed frequencies, but depend on the crystal oscillator frequency chosen.

Since the input clock frequencies are usually running asynchronously to the timer Start/Stop control bit, a 1 clock cycle error may result. This error results when the Start/Stop occurs just after the clock edge (max error). To minimize this error on all clocks an independent prescaler is used for each timer and is designed so that its Start/Stop error is less than 1 clock cycle.

The count hold/gate bit in the Timer Control Register can be used to suspend the timer operation in modes 0, 1, and 2 (in mode 3 it is the trigger input). Suspending the tim-

er causes the same synchronization error that starting the timer does. The range of errors is specified in Table V.

TABLE V. Maximum Synchronization Errors

Clock Selected	Error
External	+ Ext. Clock Period
Crystal	+ 1 Crystal Clock Period
Crystal/4	+ 1 Crystal Clock Period
10.7 kHz	+ 32 μ s
1 kHz	+ 32 μ s
100 Hz	+ 32 μ s
10 Hz	+ 32 μ s
1 Hz	+ 32 μ s

MODES OF OPERATION

Bits M0 and M1 in the Timer Control Registers are used to specify the modes of operation. The mode selection is described in Table VI.

TABLE VI. Programmable Timer Modes of Operation

M1	M0	Function	Modes
0	0	Single Pulse Generator	Mode 0
0	1	Rate Generator, Pulse Output	Mode 1
1	0	Square Wave Output	Mode 2
1	1	Retriggerable One Shot	Mode 3

MODE 0: SINGLE PULSE GENERATOR

When the timer is in this mode the output will be initially low if the Timer Start/Stop bit is low (stopped). When this mode is initiated the timer output will go high on the next falling edge of the prescaler's input clock, the contents of the

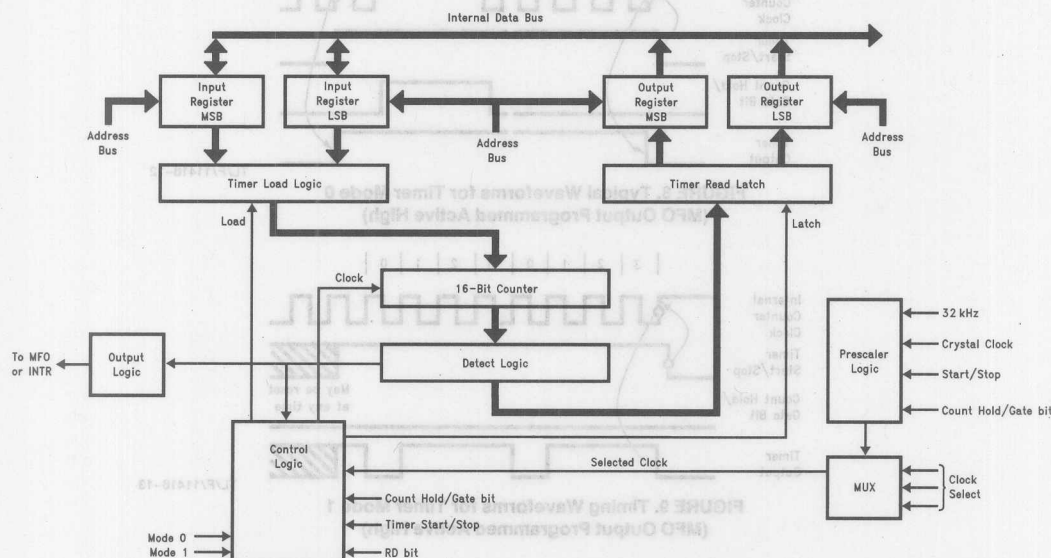

FIGURE 7. LV8571A Timer Block Diagram

TL/F/11416-11

Functional Description (Continued)

input data registers are loaded into the timer. The output will stay high until the counter reaches zero. At zero the output is reset. The result is an output pulse whose duration is equal to the input clock period times the count value (N) loaded into the input data register. This is shown in *Figure 8*.

$$\text{Pulse Width} = \text{Clock Period} \times N$$

An interrupt is generated when the zero count is reached. This can be used for one-time interrupts that are set to occur a certain amount of time in the future. In this mode the Timer Start/Stop bit (TSS) is automatically reset upon zero detection. This removes the need to reset TSS before starting another operation.

The count down operation may be temporarily suspended either under software control by setting the Count Hold/Gate bit in the timer register high, or in hardware by setting the G0 or G1 pin high.

The above discussion assumes that the MFO output is programmed to be non-inverting outputs (active high). If the polarity of the output waveform is wrong for the application the polarity can be reversed by configuring the Output Mode Register. The drive configuration can also be programmed to be push pull or open drain.

MODE 1: RATE GENERATOR

When operating in this mode the timer will operate continuously. Before the timer is started its output is low. When the timer is started the input data register contents are loaded into the counter on the negative clock edge and the output is set high (again assuming the Output Mode Register is programmed active high). The timer will then count down to zero. Once the zero count is reached the output goes low

for one clock period of the timer clock. Then on the next clock the counter is reloaded automatically and the count-down repeats itself. The output, shown in *Figure 9*, is a waveform whose pulse width and period is determined by N, the input register value, and the input clock period:

$$\text{Period} = (N + 1) (\text{Clock Period})$$

$$\text{Pulse Width} = \text{Clock Period}$$

Again, the output polarity is controllable as in mode 0. If enabled, an interrupt is generated whenever the zero count is reached. This can be used to generate a periodic interrupt.

MODE 2: SQUARE WAVE GENERATOR

This mode is also cyclic but in this case a square wave rather than a pulse is generated. The output square wave period is determined by the value loaded into the timer input register. This period and the duty cycle are:

$$\text{Period} = 2(N + 1) (\text{Clock Period}) \quad \text{Duty Cycle} = 0.5$$

When the timer is stopped the output will be low, and when the Start/Stop bit is set high the timer's counter will be loaded on the next clock falling transition and the output will be set high.

The output will be toggled after the zero count is detected and the counter will then be reloaded, and the cycle will continue. Thus, every $N + 1$ counts the output gets toggled, as shown in *Figure 10*. Like the other modes the timer operation can be suspended by setting the count hold/gate bit (CHG) in the Timer Control Register. An interrupt will be generated every falling edge of the timer output, if enabled.

FIGURE 8. Typical Waveforms for Timer Mode 0 (MFO Output Programmed Active High)

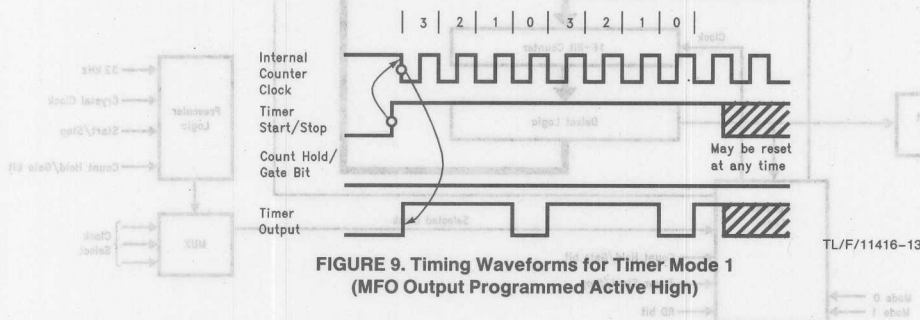

FIGURE 9. Timing Waveforms for Timer Mode 1 (MFO Output Programmed Active High)

Functional Description (Continued)

FIGURE 10. Timing Waveforms for Timer Mode 2 (MFO Output Programmed Active High)

MODE 3: RETRIGGERABLE ONE SHOT

Once the timer **Start/Stop** bit is set the output stays inactive, and nothing happens until the **Count Hold/Gate (CHG)** bit is set in the timer control register. When a transition occurs the one shot output is set active immediately; the counter is loaded with the value in the input register on the next transition of the input clock and the countdown begins. If a retrigger occurs, regardless of the current counter value, the counters will be reloaded with the value in the input register and the counter will be restarted without changing the output state. See *Figure 11*. A trigger count can occur at any time during the count cycle. In this mode the timer will output a single pulse whose width is determined by the value in the input data register (N) and the input clock period.

$$\text{Pulse Width} = \text{Clock Period} \times N$$

The timer will generate an interrupt only when it reaches a count of zero. This timer mode is useful for continuous “watch dog” timing, line frequency power failure detection, etc.

READING THE TIMERS

National has discovered that some users may encounter unacceptable error rates for their applications when reading the timers on the fly asynchronously. When doing asynchronous reads of the timers, an error may occur. The error is that a successive read may be larger than the previous read. Experimental results indicate that the typical error rate is approximately one per 29000 under the following conditions:

Timer clock frequency of 5 MHz.

Computer: 386/33 MHz PC/AT

Program: Microsoft 'C' 6.0, reading and saving timer contents in a continuous loop.

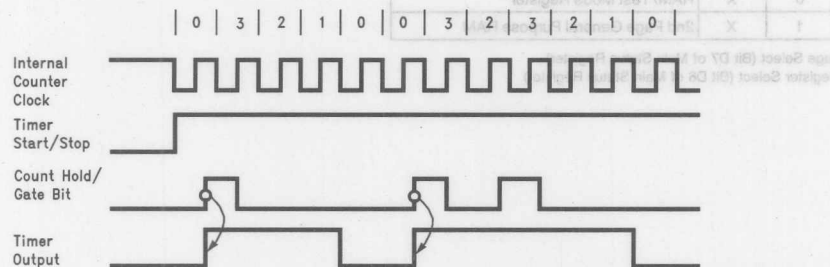

FIGURE 11. Timing Waveforms for Timer Mode 3, MFO Output Programmed Active High

Those users who find the error rate unacceptable may reduce the problem effectively to zero by employing a hardware work-around that synchronizes the writing of the read bit to the timer control register with respect to the decrementing clock. Refer to *Figure 1* in Appendix A, for a suggested hardware work-around.

A software work-around can reduce the errors but not as substantial as a hardware work-around. Software work-arounds are based on observations that the read following a bad read appeared to be valid.

This problem concerns statistical probability and is similar to metastability issues. For more information on metastability, refer to 1991 IEEE transactions on Custom Integrated Circuits Conference, paper by T.J. Gabara of AT&T Bell Laboratories, page 29.4.1.

Normally reading the timer data register addresses, 0FH and 10H for Timer 0 and 11H and 12H for Timer 1 will result in reading the input data register which contains the preset value for the timers.

To read the contents of a timer, the μP first sets the timer read bit in the appropriate Timer Control Register high. This will cause the counter's contents to be latched to 2–8 bit output registers, and will enable these registers to be read if the μP reads the timer's input data register addresses. On reading the LSB byte the timer read bit is internally reset and subsequent reads of the timer locations will return the input register values.

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 32 locations at one time. An internal switching scheme provides a total of 67 locations.

This complete address space is organized into two pages. Page 0 contains two blocks of control registers, timers, real time clock counters, and special purpose RAM, while page 1 contains general purpose RAM. Using two blocks enables the 9 control registers to be mapped into 5 locations. The only register that does not get switched is the Main Status Register. It contains the page select bit and the register select bit as well as status information.

A memory map is shown in *Figure 2* and register addressing in *Table VII*. They show the name, address and page locations for the LV8571A.

10	0	X	Day of Month Time Save RAM

1 PS—Page Select (Bit D7 of Main Status Register)

2 RS—Register Select (Bit D6 of Main Status Register)

MAIN STATUS REGISTER

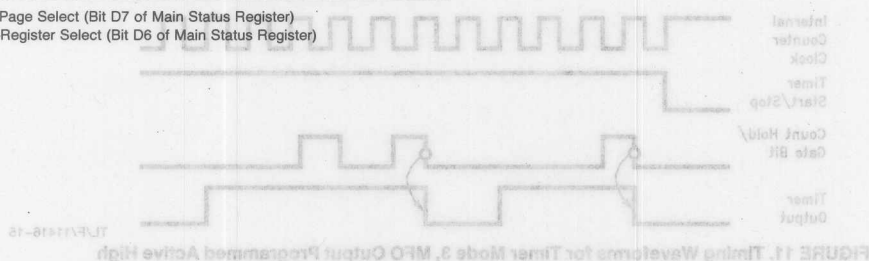

TL/F/11416-16

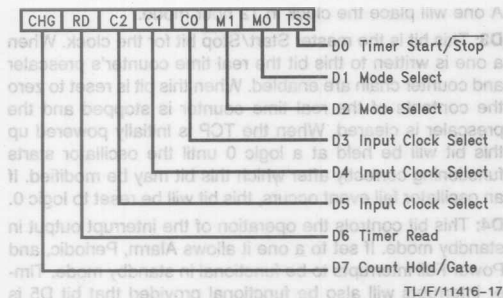

The Main Status Register is always located at address 0 regardless of the register block or the page selected.

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3-D5 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1-D5: These five bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μP will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PFAIL pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1, D3-D5 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D6 and D7: These bits are Read/Write bits that control which register block or RAM page is to be selected. Bit D6 controls the register block to be accessed (see memory map). The memory map of the clock is further divided into two memory pages. One page is the registers, clock and timers, and the second page contains 31 bytes of general purpose RAM. The page selection is determined by bit D7.

These registers control the operation of the timers. Each timer has its own register.

D0: This bit will Start (1) or Stop (0) the timer. When the timer is stopped the timer's prescaler and counter are reset, and the timer will restart from the beginning when started again. In mode 0 on time out the TSS bit is internally reset.

D1 and D2: These control the count mode of the timers. See Table VI.

D3–D5: These bits control which clock signal is applied to the timer's counter input. Refer to Table IV for details.

D6: This is the read bit. If a one is written into this location it will cause the contents of the timer to be latched into a holding register, which can be read by the μP at any time. Reading the least significant byte of the timer will reset the RD bit. The timer read cycle can be aborted by writing RD to zero.

D7: The CHG bit has two mode dependent functions. In modes 0 through 2 writing a one to this bit will suspend the timer operation (without resetting the timer prescaler). However, in mode 3 this bit is used to trigger or re-trigger the count sequence as with the gate pins. If retriggering is desired using the CHG bit, it is not necessary to write a zero to this location prior to the re-trigger. The action of further writing a one to this bit will re-trigger the count.

PERIODIC FLAG REGISTER

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0–D5 are read only bits, D6 and D7 are read/write.

read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure might be caused are: failure of the crystal, shorting OSC IN or OSC OUT to GND or V_{CC} , removal of crystal, removal of battery when in the battery backed mode (when a "0" is written to D6), lowering the voltage at the V_{BB} pin to a value less than 2.2V when in the battery backed mode. Bit D6 is automatically set to 1 on initial power-up or an oscillator fail event. The oscillator fail flag is reset by writing a one to the clock start/stop bit in the Real Time Mode Register, with the crystal oscillating.

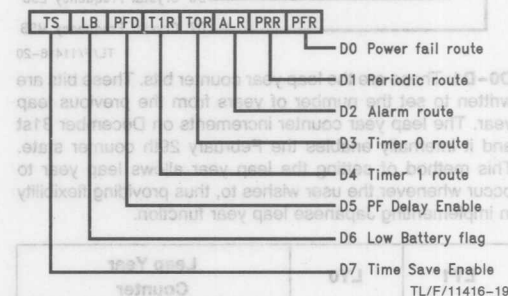

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the LV8571A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to V_{CC} -0.4V.

For single supply mode operation, the V_{BB} pin should be connected to GND and the P_{FAIL} pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table VII). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

INTERRUPT ROUTING REGISTER

D0–D4: The lower 5 bits of this register are associated with the main interrupt sources created by this chip. The purpose of this register is to route the interrupts to either the MFO (multi-function pin), or to the main interrupt pin. When any bit is set the associated interrupt signal will be sent to the MFO pin, and when zero it will be sent to the INTR pin.

Functional Description (Continued)

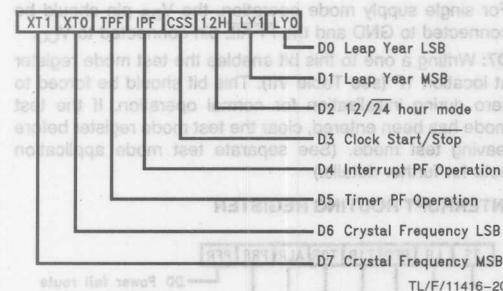

D5: The Delay Enable bit is used when a power fail occurs. If this bit is set, a 480 μ s delay is generated internally before the μ P interface is locked out. This will enable the μ P to access the registers for up to 480 μ s after it receives a power fail interrupt. After a power failure is detected but prior to the 480 μ s delay timing out, the host μ P may force immediate lock out by resetting the Delay Enable bit. Note if this bit is a 0 when power fails then after a delay of 30 μ s min/63 μ s max the μ P cannot read the chip.

D6: This read only bit is set and reset by the voltage at the V_{BB} pin. It can be used by the μ P to determine whether the battery voltage at the V_{BB} pin is getting too low. A comparator monitors the battery and when the voltage is lower than 2.1V (typical) this bit is set. The power fail interrupt must be enabled to check for a low battery voltage.

D7: Time Save Enable bit controls the loading of real-time-clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

D0-D1: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

D2: The count mode for the hours counter can be set to either 24 hour mode or 12 hour mode with AM/PM indicator. A one will place the clock in 12 hour mode.

D3: This bit is the master Start/Stop bit for the clock. When a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped and the prescaler is cleared. When the TCP is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Timer interrupts will also be functional provided that bit D5 is also set. Note that the MFO and INTR pins are configured as open drain in standby mode.

If bit D4 is set to a zero then interrupt control register 0 and bits D6 and D7 of interrupt control register 1 will be reset when the TCP enters the standby mode ($V_{BB} > V_{CC}$). They will have to be re-configured when system (V_{CC}) power is restored.

D5: This bit controls the operation of the timers in standby mode. If set to a one the timers will continue to function when the TCP is in standby mode. The input pins TCK, G0, G1 are locked out in standby mode, and cannot be used.

Therefore external control of the timers is not possible in standby mode. Note also that MFO and T1 pins are automatically reconfigured open drain during standby.

D6 and D7: These two bits select the crystal clock frequency as per the following table:

XT1	XT0	Crystal Frequency
0	0	32.768 kHz
0	1	4.194304 MHz
1	0	4.9152 MHz
1	1	32.000 kHz

All bits are Read/Write, and any mode written into this register can be determined by reading the register. On initial power up these bits are random.

OUTPUT MODE REGISTER

Functional Description (Continued)

D0 and D1: These bits are available as general purpose RAM.

D2: This bit, when set to a one makes the INTR output pin active high, and when set to a zero, it makes this pin active low.

D3: This bit controls whether the INTR pin is an open drain or push-pull output. A one indicates push-pull.

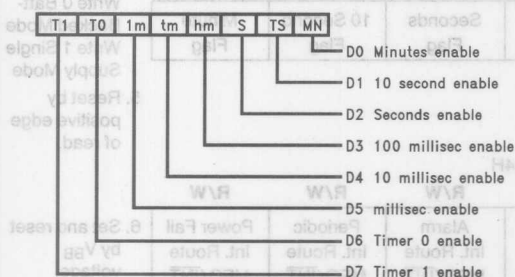

D4: This bit, when set to a one makes the MFO output pin active high, and when set to a zero, it makes this pin active low.

D5: This bit controls whether the MFO pin is an open drain or push-pull output. A one indicates push-pull.

D6 and D7: These bits are used to program the signal appearing at the MFO output, as follows:

D7	D6	MFO Output Signal
0	0	2nd Interrupt
0	1	Timer 0 Waveform
1	X	Buffered Crystal Oscillator

INTERRUPT CONTROL REGISTER 0

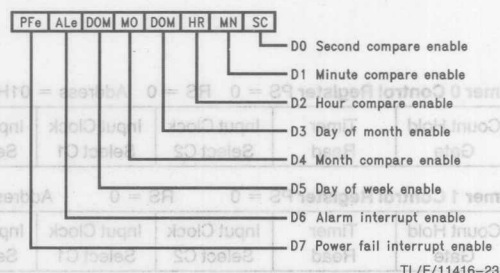

D0-D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the periodic time chosen, but after the first interrupt all subsequent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task

switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin.

D6 and D7: These are individual timer enable bits. A one written to these bits enable the timers to generate interrupts to the μP .

INTERRUPT CONTROL REGISTER 1

D0-D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the "always equal" state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If battery backed mode is selected then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when PFAIL = 0. If battery backed mode is selected then this bit is controlled by D4 of the Real Time Mode Register.

This bit also enables the low battery detection analog circuitry.

If the user wishes to mask the power fail interrupt, but utilize the analog circuitry, this bit should be enabled, and the Routing Register can be used to route the interrupt to the MFO pin. The MFO pin can then be left open or configured as the Timer 0 or buffered oscillator output.

ic Flag Register.

- Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
- Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1, 2, 3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.
- After power on (V_{CC} and V_{BB} powered), select the correct crystal frequency bits (D7, D6 in the Real Time Mode Register) as shown in Table 1.

Table 1

Frequency	D7	D6
32.768 KHz	0	0
4.194304 MHz	0	1
4.9152 MHz	1	0
32.0 KHz	1	1

- Enter a software loop that does the following:

Set a 3 second(approx) software counter. The crystal oscillator may take 1 second to start.

- Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Make sure the crystal select bits remain the same as in step 1. Under normal operation, this bit can be set only if the oscillator is running. During the software loop, RAM, real time counters, output configu-

IF a 1, go to 5.1 If this bit remains a 1 after 3 seconds, then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 M Ω .

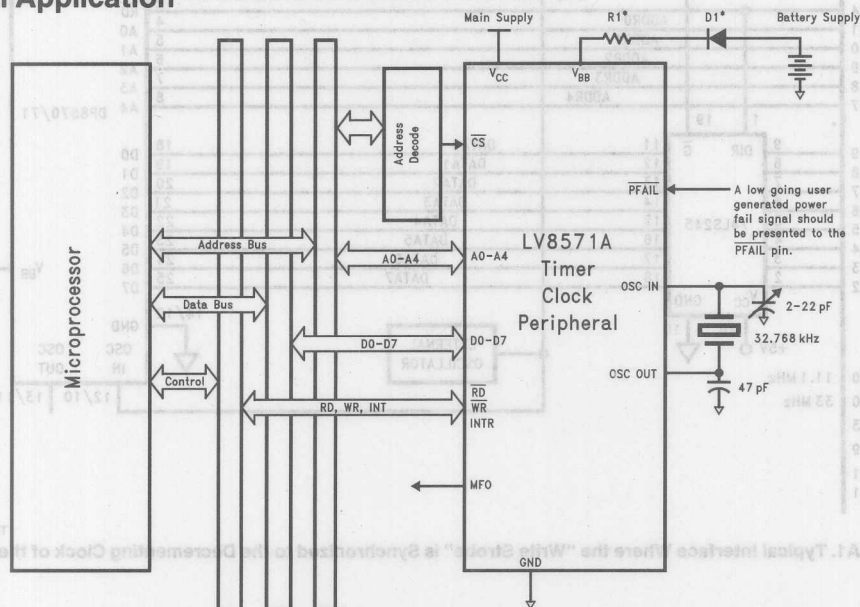

IF a 0, then the oscillator is running, go to step 7.

- Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the OSC fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder, bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation.

The only method to ensure the chip is in the battery backed mode is to measure the waveform at the OSC OUT pin. If the battery backed mode was selected successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC} . The measurement should be made with a high impedance low capacitance probe (10 M Ω , 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.

- Write a 1 to bit D7 of Interrupt Control Register 1. This action enables the PFAIL pin and associated circuitry.
- Write a 1 to bit D4 of the Real Time Mode Register. This action ensures that bit D7 of Interrupt Control Register 1 remains a 1 when $V_{BB} > V_{CC}$ (standby mode).
- Initialize the rest of the chip as needed.

Typical Application

*These components may be necessary to meet UL requirements for lithium batteries. Consult battery manufacturer.

LV8572A Low Voltage Real Time Clock (RTC)

General Description

The LV8572A is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports. The address space is organized as 2 software selectable pages of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, and the Time Save RAM. Any of the RAM locations that are not being used for their intended purpose may be used as general purpose CMOS RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week, day of month and day of year counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the crystal and two capacitors. The choice of crystal frequency is program selectable.

Power failure logic and control functions have been integrated on chip. This logic is used by the RTC to issue a power fail interrupt, and lock out the μP interface. The time power

fails may be logged into RAM automatically when $V_{BB} > V_{CC}$. Additionally, two supply pins are provided. When $V_{BB} > V_{CC}$, internal circuitry will automatically switch from the main supply to the battery supply. Status bits are provided to indicate initial application of battery power, system power, and low battery detect. (Continued)

Features

- $3.3V \pm 10\%$ supply
- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week and day of years counters
 - Four selectable oscillator frequencies
 - Parallel resonant oscillator
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, and power fail interrupts
- Up to 44 bytes of CMOS RAM

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: For $F_{OSC} = 4.194304$ or 4.9152 MHz, V_{BB} minimum = 2.8V. In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$.

Single Supply Mode: Data retention voltage is 2.2V min.

In single Supply Mode (Power connected to V_{CC} pin) $3.0V \leq V_{CC} \leq 3.6$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

AC Electrical Characteristics

$V_{CC} = 3.3V \pm 10\%$, $V_{BB} = 2.5V$, $V_{PFAIL} > V_{IH}$, $C_L = 100$ pF (unless otherwise specified)

Symbol	Parameter	Min	Max	Units
READ TIMING				
t_{AR}	Address Valid Prior to Read Strobe	10		ns
t_{RW}	Read Strobe Width (Note 8)	100		ns
t_{CD}	Chip Select to Data Valid Time		100	ns
t_{RAH}	Address Hold after Read (Note 9)	2		ns
t_{RD}	Read Strobe to Valid Data		90	ns
t_{DZ}	Read or Chip Select to TRI-STATE		80	ns
t_{RCH}	Chip Select Hold after Read Strobe (Note 9)	0		ns
t_{DS}	Minimum Inactive Time between Read or Write Accesses	70		ns

WRITE TIMING

t_{AW}	Address Valid before Write Strobe	10		ns
t_{WAH}	Address Hold after Write Strobe (Note 9)	2		ns
t_{CW}	Chip Select to End of Write Strobe	110		ns
t_{WW}	Write Strobe Width (Note 10)	100		ns
t_{DW}	Data Valid to End of Write Strobe	70		ns
t_{WDH}	Data Hold after Write Strobe (Note 9)	2		ns
t_{WCH}	Chip Select Hold after Write Strobe (Note 9)	0		ns

INTERRUPT TIMING

t_{ROLL}	Clock Rollover to \overline{INTR} Out is Typically 20 μ s			
------------	---	--	--	--

Note 8: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 9: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 10: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output	1.3V
Reference Levels	
TRI-STATE Reference	Active High +0.5V
Levels (Note 12)	Active Low –0.5V

Note 11: $C_L = 100$ pF, includes jig and scope capacitance.

Note 12: $S_1 = V_{CC}$ for active low to high impedance measurements.

$S_1 = GND$ for active high to high impedance measurements.

$S_1 =$ open for all other timing measurements.

Capacitance ($T_A = 25^\circ C$, $f = 1$ MHz)

Symbol	Parameter (Note 13)	Typ	Units
C_{IN}	Input Capacitance	5	pF
C_{OUT}	Output Capacitance	7	pF

Note 13: This parameter is not 100% tested.

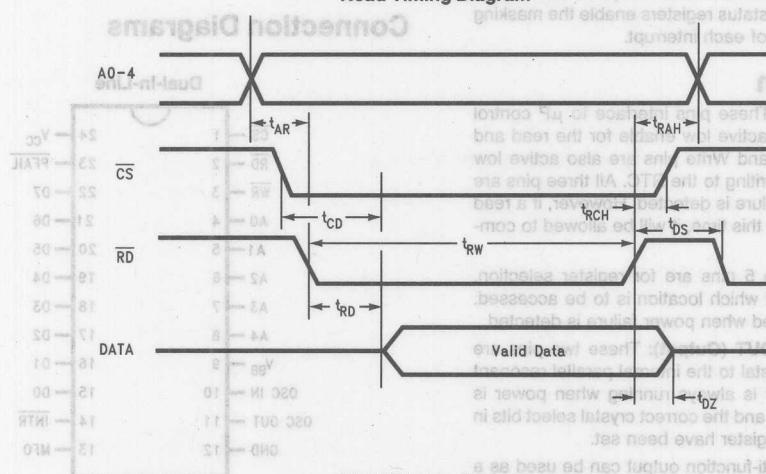

Note 14: Output rise and fall times 25 ns max (10%–90%) with 100 pF load.

General Description (Continued)

The LV8572A's interrupt structure provides three basic types of interrupts: Periodic, Alarm/Compare, and Power Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

Pin Description

CS, RD, WR (Inputs): These pins interface to μ P control lines. The $\overline{\text{CS}}$ pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the RTC. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} , and the correct crystal select bits in the Real Time Mode Register have been set.

MFO (Output): The multi-function output can be used as a second interrupt output for interrupting the μ P. This pin can also provide an output for the oscillator. The MFO output is configured as push-pull, active high for normal or single power supply operation and as an open drain during standby mode ($V_{\text{BB}} > V_{\text{CC}}$). If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} .

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The INTR output is permanently configured active low, open drain. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} .

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μ P's data bus and are used to read from and write to the RTC. When the PFAIL pin goes low and a write is not in progress, these pins are at TRI-STATE.

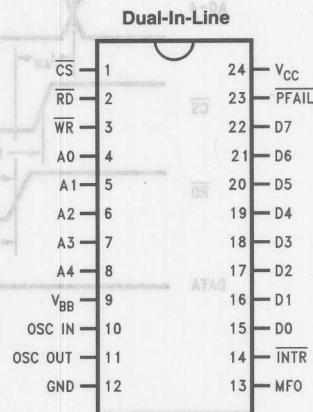

PFAIL (Input): In battery backed mode, this pin can have a digital signal applied to it via some external power detection logic. When PFAIL = logic 0 the RTC goes into a lockout mode, in a minimum of 30 μ s or a maximum of 63 μ s unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

V_{BB} (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be used then this pin must be tied to ground, the RTC programmed for single power supply only, and power applied to the V_{CC} pin.

V_{CC}: This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

functional blocks is given in Figure 1.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management

select either page. Figure 2 shows the basic concept. Page 0 contains all the clock timer functions, while page 1 has scratch pad RAM. The control registers are split into two separate blocks to allow page 1 to be used entirely as scratch pad RAM. Again a control bit in the Main Status Register is used to select either control register block.

FIGURE 2. LV8572A Internal Memory Map

Functional Description (Continued)

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of 1 M Ω . The user should be aware that the control registers will contain random data. The first task to be carried out in an initialization routine is to start the oscillator by writing to the crystal select bits in the Real Time Mode Register. If the LV8572A is configured for single supply mode, an extra 50 μ A may be consumed until the crystal select bits are programmed. The user should also ensure that the RTC is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 10 bytes of counters, which count from 1/100 of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, day of year, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Also note that the day of year counter is 12 bits long and occupies two addresses. Upon initial application of power the counters will contain random information.

READING THE CLOCK: VALIDATED READ

Since clocking of the counter occurs asynchronously to reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time

Save Enable bit (D7) of the Time Save Control Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the RTC or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

The above method is useful when the entire clock is being corrected. If one location is being updated the clock need not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the 1/100 of a second periodic interrupt. Then wait an additional 16 μ s, and then write the data to the clock.

PRESALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3). The crystal frequency that can be selected are: 32 kHz, 32.768 kHz, 4.9152 MHz, and 4.194304 MHz.

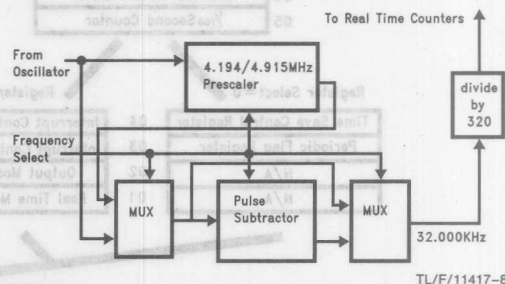

FIGURE 3. Programmable Clock Prescaler Block

Functional Description (Continued)

The oscillator is programmed via the Real Time Mode Register to operate at various frequencies. The crystal oscillator is designed to offer optimum performance at each frequency. Thus, at 32.768 kHz the oscillator is configured as a low frequency and low power oscillator. At the higher frequencies the oscillator inverter is reconfigured. In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the **load capacitance** specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

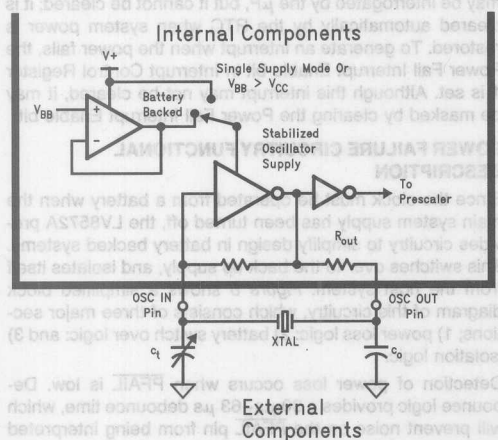

FIGURE 4. Oscillator Circuit Diagram

XTAL	Co	Ct	Rout (Switched Internally)
32/32.768 kHz	47 pF	2 pF–22 pF	150 kΩ to 350 kΩ
4.194304 MHz	68 pF	0 pF–80 pF	500Ω to 900Ω
4.9152 MHz	68 pF	29 pF–49 pF	500Ω to 900Ω

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The RTC has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and also Figure 5 and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Page Select	Address
Main Status Register	X	X	00H
Periodic Flag Register	0	0	03H
Interrupt Control Register 0	1	0	03H
Interrupt Control Register 1	1	0	04H
Output Mode Register	1	0	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all RTC interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the RTC to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system. (The Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.) Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1–D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm comparisons that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the Alarm interrupt enable bit is set (see Figure 5).

Disabling the periodic interrupts will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see Figure 5).

To clear a flag in bits D2 and D3 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Functional Description (Continued)

Interrupts Fall Into Three Categories:

1. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
2. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.
3. The Power Fail Interrupt: Issued upon recognition of a power fail condition by the internal sensing logic. The power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The RTC then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 03 (BCD), the minutes compare with 15 (BCD) and the faster counters with 00 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see

Figure 5. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μP clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μP , but it cannot be cleared; it is cleared automatically by the RTC when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the LV8572A provides circuitry to simplify design in battery backed systems. This switches over to the back up supply, and isolates itself from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when PFAIL is low. De-bounce logic provides a 30 μs –63 μs debounce time, which will prevent noise on the PFAIL pin from being interpreted as a system failure. After 30 μs –63 μs the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

XTAL	C ₀	C ₁	OUT (switched internally)
32.768 KHz	47 pF	2 pF–22 pF	150 k Ω to 350 k Ω
4.194304 MHz	68 pF	0 pF–80 pF	500 Ω to 800 Ω
4.192 MHz	68 pF	28 pF–48 pF	500 Ω to 800 Ω

TL/F/11417-10

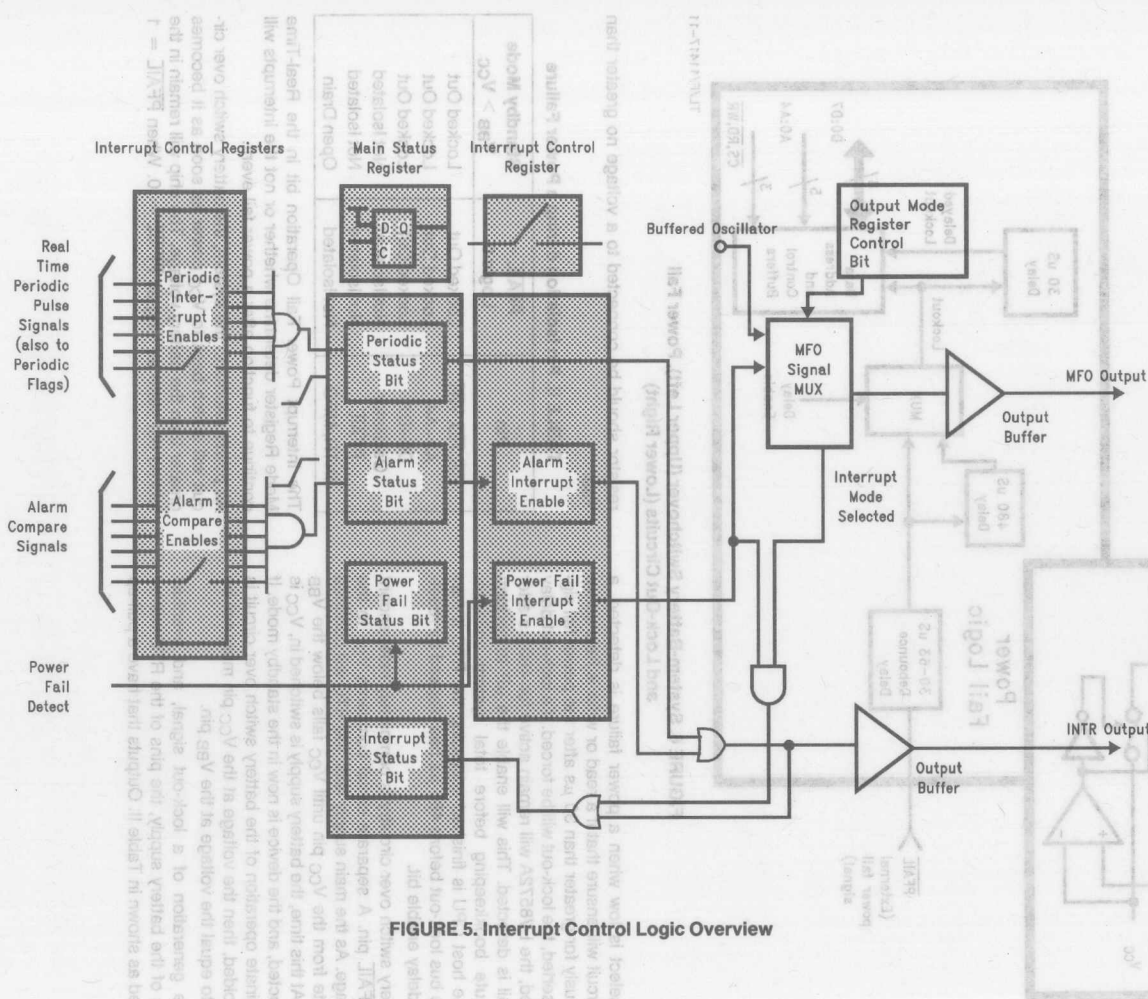

FIGURE 5. Interrupt Control Logic Overview

Functional Description (Continued)

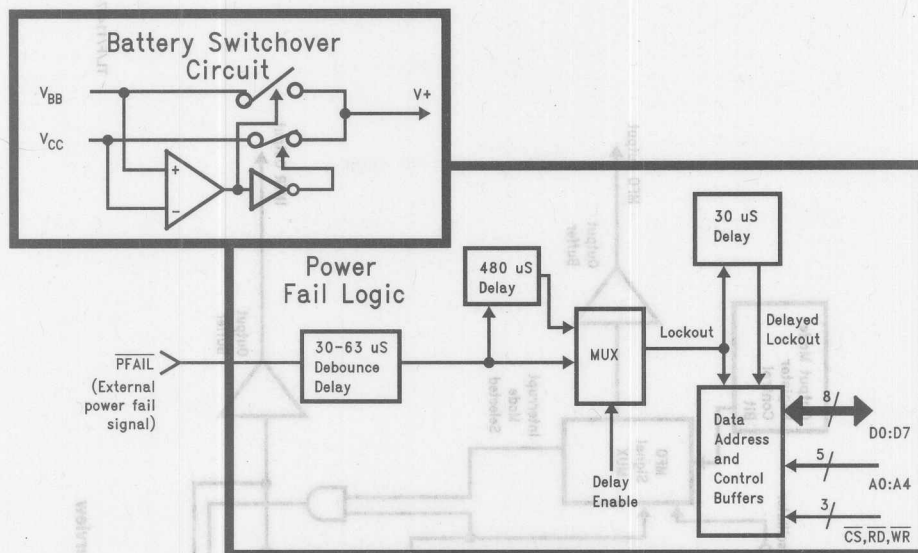

FIGURE 6. System-Battery Switchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

TL/F/11417-11

If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than 30 μ s after the power fail signal is asserted, the lock-out will be forced. If a lock-out delay is enabled, the LV8572A will remain active for 480 μ s after power fail is detected. This will enable the μ P to perform last minute bookkeeping before total system collapse. When the host CPU is finished accessing the RTC it may force the bus lock-out before 480 μ s has elapsed by resetting the delay enable bit.

The battery switch over circuitry is completely independent of the $\overline{\text{PFAIL}}$ pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the RTC will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the RTC will be configured as shown in Table II. Outputs that have a pull-up

resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	$\overline{\text{PFAIL}} =$ Logic 0	Standby Mode $V_{BB} > V_{CC}$
$\overline{\text{CS}}, \text{RD}, \text{WR}$	Locked Out	Locked Out
A0-A4	Locked Out	Locked Out
D0-D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
$\overline{\text{PFAIL}}$	Not Isolated	Not Isolated
INTR, MFO	Not Isolated	Open Drain

The Interrupt Power Fail Operation bit in the Real-Time Mode Register determine whether or not the interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as $\overline{\text{PFAIL}} = 0$. When $\overline{\text{PFAIL}} = 1$

Functional Description (Continued)

the chip is unlocked, but only after another 30 μ s min \rightarrow 63 μ s max debounce time. The system designer must ensure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no external interrupt will be issued. Note that the linear power fail circuitry is switched off automatically when using V_{BB} in standby mode.

LOW BATTERY, INITIAL POWER ON DETECT, AND POWER FAIL TIME SAVE

There are three other functions provided on the LV8572A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, a low battery detect circuit, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

Another status bit is the low battery detect. This bit is set only when the clock is operating under the V_{CC} pin, and when the battery voltage is determined to be less than 2.1V (typical). When the power fail interrupt enable bit is low, it disables the power fail circuit and will also shut off the low battery voltage detection circuit as well.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the PFAIL pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The LV8572A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC} and PFAIL pins. The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits. Until the crystal select bits are initialized, the LV8572A may consume about 50 μ A due to arbitrary oscillator selection at power on.

(This extra 50 μ A is not consumed if the battery backed mode is selected).

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 28 locations at one time. An internal switching scheme provides a total of 61 locations.

This complete address space is organized into two pages. Page 0 contains two blocks of control registers, timers, real time clock counters, and special purpose RAM, while page 1 contains general purpose RAM. Using two blocks enables the 9 control registers to be mapped into 5 locations. The only register that does not get switched is the Main Status Register. It contains the page select bit and the register select bit as well as status information.

A memory map is shown in Figure 2 and register addressing in Table III. They show the name, address and page locations for the LV8572A.

2 RS—Register Select (Bit D6 of Main Status Register)

Functional Description (Continued)

MAIN STATUS REGISTER

TL/F/11417-12

The Main Status Register is always located at address 0 regardless of the register block or the page selected.

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1–D3: These three bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μ P will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PFAIL pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1 and D3 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D4–D5: General purpose RAM bits.

D6 and D7: These bits are Read/Write bits that control which register block or RAM page is to be selected. Bit D6 controls the register block to be accessed (see memory map). The memory map of the clock is further divided into two memory pages. One page is the registers, clock and timers, and the second page contains 31 bytes of general purpose RAM. The page selection is determined by bit D7.

PERIODIC FLAG REGISTER

TL/F/11417-13

Functional Description (Continued)

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0–D5 are read only bits, D6 and D7 are read/write.

D0–D5: These bits are set by the real time rollover events: (Time Change = 1). The bits are reset when the register is read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure might be caused are: failure of the crystal, shorting OSC IN or OSC OUT to GND or V_{CC} , removal of crystal, removal of battery when in the battery backed mode (when a "0" is written to D6), lowering the voltage at the V_{BB} pin to a value less than 2.2V when in the battery backed mode. Bit D6 is automatically set to 1 on initial power-up or an oscillator fail event. The oscillator fail flag is reset by writing a one to the clock start/stop bit in the Real Time Mode Register, with the crystal oscillating.

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the LV8572A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to V_{CC} – 0.4V.

For single supply mode operation, the V_{BB} pin should be connected to GND and the PFAIL pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table III). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

TIME SAVE CONTROL REGISTER

TL/F/11417-14

D0–D4: General purpose RAM bits.

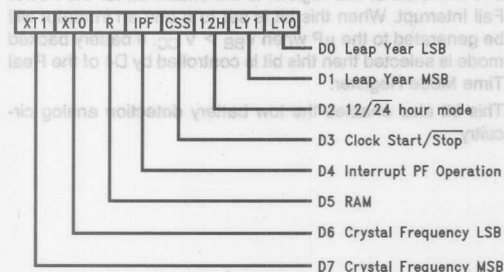

access the registers for up to 480 μ s after it receives a power fail interrupt. After a power failure is detected but prior to the 480 μ s delay timing out, the host μ P may force immediate lock out by resetting the Delay Enable bit. Note if this bit is a 0 when power fails then after a delay of 30 μ s min/63 μ s max the μ P cannot read the chip.

D6: This read only bit is set and reset by the voltage at the V_{BB} pin. It can be used by the μ P to determine whether the battery voltage at the V_{BB} pin is getting too low. A comparator monitors the battery and when the voltage is lower than 2.1V (typical) this bit is set. The power fail interrupt must be enabled to check for a low battery voltage.

D7: Time Save Enable bit controls the loading of real-time clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

TL/F/11417-15

D0-D1: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

D3: This bit is the master Start/Stop bit for the clock. When a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped and the prescaler is cleared. When the RTC is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Note that the MFO pin is configured as open drain in standby mode.

If bit D4 is set to a zero then interrupt control register and the periodic interrupt flag will be reset when the RTC enters the standby mode ($V_{BB} > V_{CC}$). They will have to be re-configured when system (V_{CC}) power is restored.

D5: General purpose RAM.

D6 and D7: These two bits select the crystal clock frequency as per the following table:

XT1	XT0	Crystal Frequency
0	0	32.768 kHz
0	1	4.194304 MHz
1	0	4.9152 MHz
1	1	32.000 kHz

All bits are Read/Write, and any mode written into this register can be determined by reading the register. On initial power up these bits are random.

OUTPUT MODE REGISTER

TL/F/11417-16

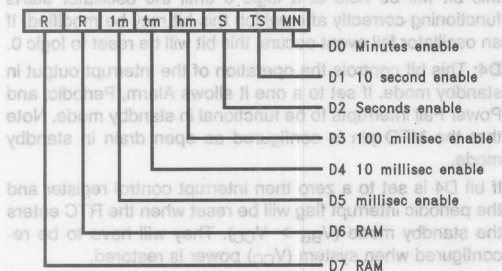

D0-D6: General Purpose RAM

Functional Description (Continued)

D7: This bit is used to program the signal appearing at the MFO output, as follows:

MFO Output Signal	
0	Power Fail Interrupt
1	Buffered Crystal Oscillator

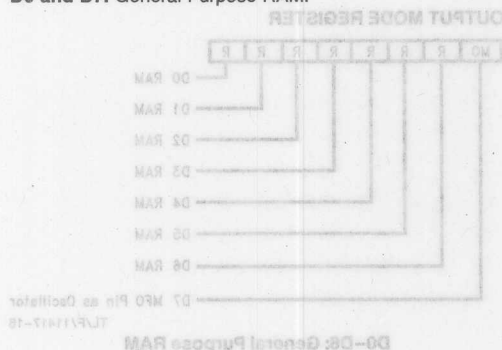

INTERRUPT CONTROL REGISTER 0

TL/F/11417-17

D0–D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the periodic time chosen, but after the first interrupt all subsequent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin.

D6 and D7: General Purpose RAM.

D0–D6: General Purpose RAM

INTERRUPT CONTROL REGISTER 1

TL/F/11417-18

D0–D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the "always equal" state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If battery backed mode is selected then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when $V_{BB} > V_{CC}$. If battery backed mode is selected then this bit is controlled by D4 of the Real Time Mode Register.

This bit also enables the low battery detection analog circuitry.

D0–D7: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

Application Hints

Suggested Initialization Procedure for LV8572A in Battery Backed Applications that use the V_{BB} Pin.

1. Enter the test mode by writing a 1 to bit D7 in the Periodic Flag Register.
2. Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
3. Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1,2,3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.
4. After power on (V_{CC} and V_{BB} powered), select the correct crystal frequency bits (D7, D6 in the Real Time Mode Register) as shown in Table IV.

TABLE IV

Frequency	D7	D6
32.768 kHz	0	0
4.194304 MHz	0	1
4.9152 MHz	1	0
32.0 kHz	1	1

5. Enter a software loop that does the following:
Set a 3 second(approx) software counter. The crystal oscillator may take 1 second to start.
- 5.1 Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Make sure the crystal select bits re-

main the same as in step 1. Under normal operation, this bit can be set only if the oscillator is running. During the software loop, RAM, real time counters, output configuration, interrupt control and timer functions may be initialized.

6. Test bit D6 in the Periodic Flag Register:

IF a 1, go to 5.1. If this bit remains a 1 after 3 seconds, then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 M Ω .

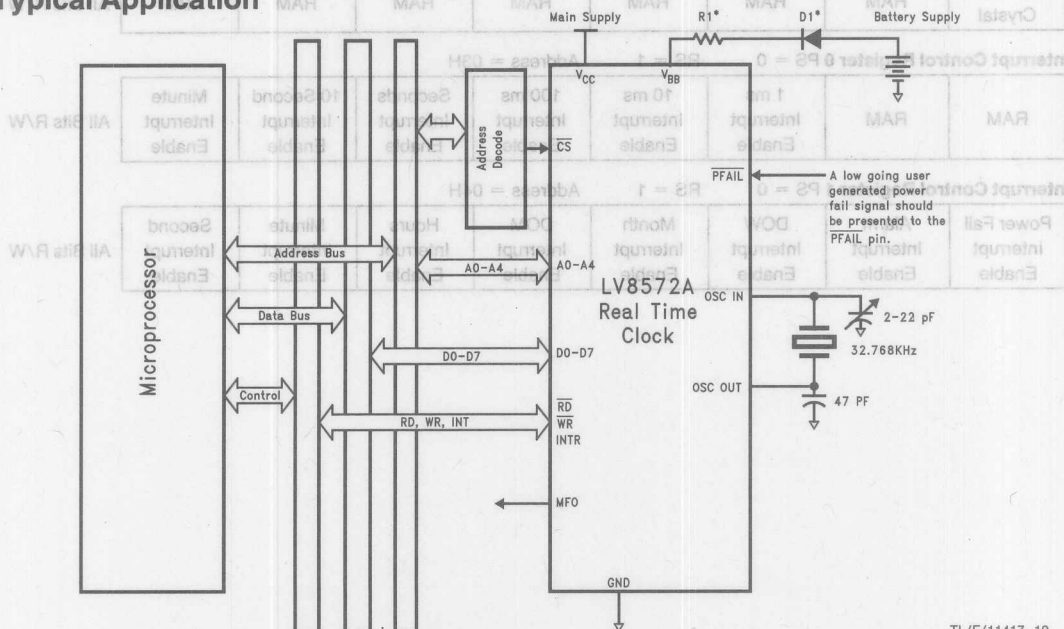

IF a 0, then the oscillator is running, go to step 7.

7. Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the OSC fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder: Bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation.

The only method to ensure the chip is in the battery backed mode is to measure the waveform at the OSC OUT pin. If the battery backed mode was selected successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC}. The measurement should be made with a high impedance low capacitance probe (10 M Ω , 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.

8. Write a 1 to bit D7 of Interrupt Control Register-1. This action enables the PFAIL pin and associated circuitry.
9. Initialize the rest of the chip as needed.

Typical Application

*These components may be necessary to meet UL requirements for lithium batteries. Consult battery manufacturer.

TL/F/11417-19

Typical Performance Characteristics

Operating Current vs Supply Voltage (Single Supply Mode)
Fosc = 32.768 kHz

Standby Current vs Power Supply Voltage
(Fosc = 32.768 kHz)

Operating Current vs Supply Voltage (Battery Backed Mode)
Fosc = 32.768 kHz,
VBB = 2.5V

Standby Current vs Power Supply Voltage
Fosc = 4.194304 MHz

LV8573A Low Voltage Real Time Clock (RTC)

General Description

The LV8573A is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports organized as one block of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, and the Time Save RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week and day of month counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the 32.768 kHz crystal and two capacitors.

Power failure logic and control functions have been integrated on chip. This logic is used by the RTC to issue a power fail interrupt, and lock out the μP interface. The time power fails may be logged into RAM automatically when $V_{BB} > V_{CC}$. Additionally, two supply pins are provided. When V_{BB}

$> V_{CC}$, internal circuitry will automatically switch from the main supply to the battery supply.

The LV8573A's interrupt structure provides three basic types of interrupts: Periodic, Alarm/Compare, and Power Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

Features

- $3.3V \pm 10\%$ supply
- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week counter
 - Parallel resonant oscillator
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, and power fail interrupts

I_{CC}	Quiescent Supply Current (Single Supply Mode) (Note 7)	$V_{BB} = GND$ $V_{IN} = V_{CC}$ or GND $F_{OSC} = 32.768$ kHz		30	μA
I_{BB}	Standby Mode Battery Supply Current (Note 7)	$V_{CC} = GND$ OSC OUT = open circuit, other pins = GND $F_{OSC} = 32.768$ kHz		8	μA
I_{BLK}	Battery Leakage	$2.2V \leq V_{BB} \leq 2.6V$ other pins at GND $V_{CC} = GND$, $V_{BB} = 2.6V$ $V_{CC} = 3.6V$, $V_{BB} = 2.2V$	-0.8	0.8	μA μA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$.

Single Supply Mode: Data retention voltage is 2.2V min.

In single Supply Mode (Power connected to V_{CC} pin) $3.0V \leq V_{CC} \leq 3.6V$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

AC Electrical Characteristics

$V_{CC} = 3.3V \pm 10\%$, $V_{BB} = 2.5V$, $V_{PFAIL} > V_{IH}$, $C_L = 100$ pF unless otherwise specified

Symbol	Parameter	Min	Max	Units
READ TIMING				
t_{AR}	Address Valid Prior to Read Strobe	10		ns
t_{RW}	Read Strobe Width (Note 8)	100		ns
t_{CD}	Chip Select to Data Valid Time		100	ns
t_{RAH}	Address Hold after Read (Note 9)	2		ns
t_{RD}	Read Strobe to Valid Data		90	ns
t_{DZ}	Read or Chip Select to TRI-STATE		80	ns
t_{RCH}	Chip Select Hold after Read Strobe (Note 9)	0		ns
t_{DS}	Minimum Inactive Time between Read or Write Accesses	70		ns
WRITE TIMING				
t_{AW}	Address Valid before Write Strobe	10		ns
t_{WAH}	Address Hold after Write Strobe (Note 9)	2		ns
t_{CW}	Chip Select to End of Write Strobe	110		ns
t_{WW}	Write Strobe Width (Note 10)	100		ns
t_{DW}	Data Valid to End of Write Strobe	70		ns
t_{WDH}	Data Hold after Write Strobe (Note 9)	2		ns
t_{WCH}	Chip Select Hold after Write Strobe (Note 9)	0		ns
INTERRUPT TIMING				
t_{ROLL}	Clock rollover to INTR out typically 20 μ s			

Note 8: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 9: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 10: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output Reference Levels	1.3V
TRI-STATE Reference Levels (Note 12)	Active High +0.5V Active Low –0.5V

Note 11: $C_L = 100$ pF, includes jig and scope capacitance.

Note 12: $S_1 = V_{CC}$ for active low to high impedance measurements.

$S_1 = GND$ for active high to high impedance measurements.

$S_1 = \text{open}$ for all other timing measurements.

Capacitance ($T_A = 25^\circ\text{C}$, $f = 1$ MHz)

Symbol	Parameter (Note 13)	Typ	Units
C_{IN}	Input Capacitance	5	pF
C_{OUT}	Output Capacitance	7	pF

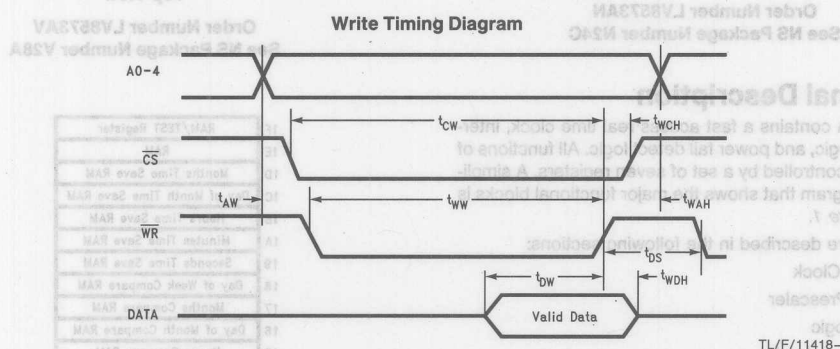

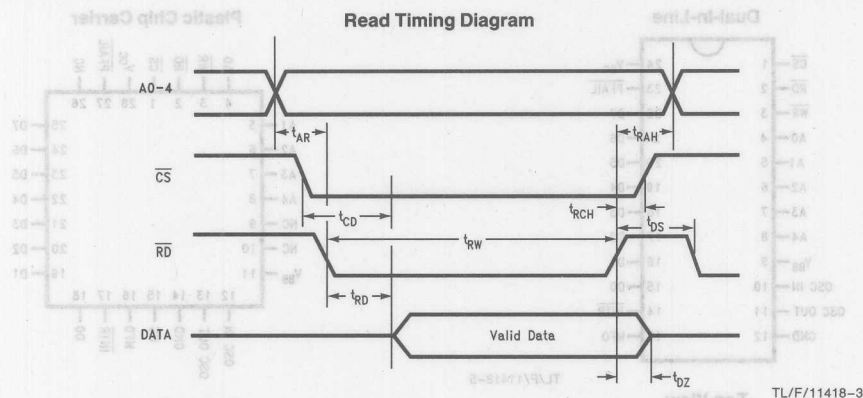

Note 13: This parameter is not 100% tested.

Note 14: Output rise and fall times 25 ns max (10%–90%) with 100 pF load.

TL/F/11418–2

Timing Waveforms

Pin Description

CS, RD, WR (Inputs): These pins interface to μP control lines. The \overline{CS} pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the RTC. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} .

MFO (Output): The multi-function output can be used as a second interrupt (Power fail) output for interrupting the μP . This pin can also provide an output for the oscillator. The MFO output is configured as push-pull, active high for normal or single power supply operation and as an open drain during standby mode ($V_{BB} > V_{CC}$). If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} .

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The \overline{INTR}

output is permanently configured active low, open drain. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} .

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μP 's data bus and are used to read from and write to the RTC. When the \overline{PFAIL} pin goes low and a write is not in progress, these pins are at TRI-STATE.

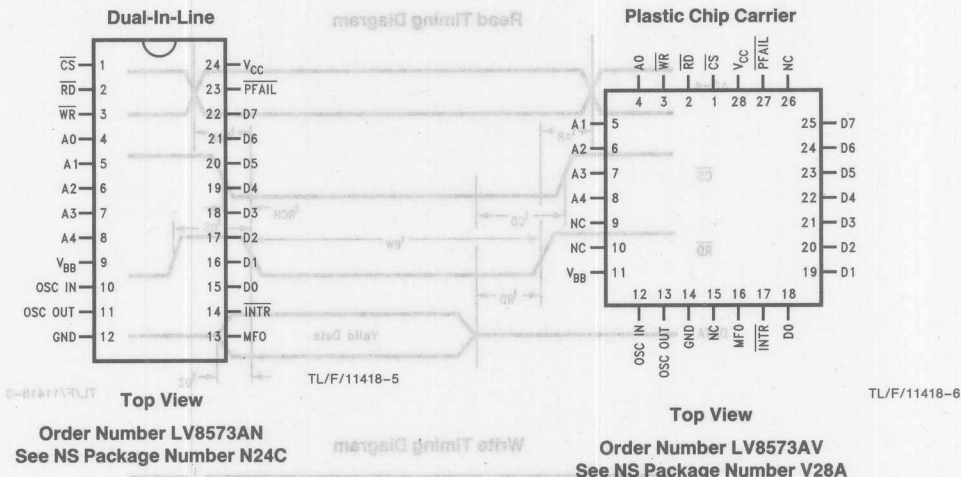

PFAIL (Input): In battery backed mode, this pin can have a digital signal applied to it via some external power detection logic. When $\overline{PFAIL} = \text{logic } 0$ the RTC goes into a lockout mode, in a minimum of 30 μs or a maximum of 63 μs unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

VBB (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be used then this pin must be tied to ground, the RTC programmed for single power supply only, and power applied to the V_{CC} pin.

VCC: This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

Connection Diagrams

Functional Description

The LV8573A contains a fast access real time clock, interrupt control logic, and power fail detect logic. All functions of the RTC are controlled by a set of seven registers. A simplified block diagram that shows the major functional blocks is given in Figure 1.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management

The memory map of the RTC is shown in the memory addressing table (Figure 2). A control bit in the Main Status Register is used to select either control register block.

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of 1 M Ω . The user should be aware that the control registers will contain random data. The user should ensure that the RTC is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 8 bytes of counters, which count from 1/100 of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Upon initial application of power the counters will contain random information.

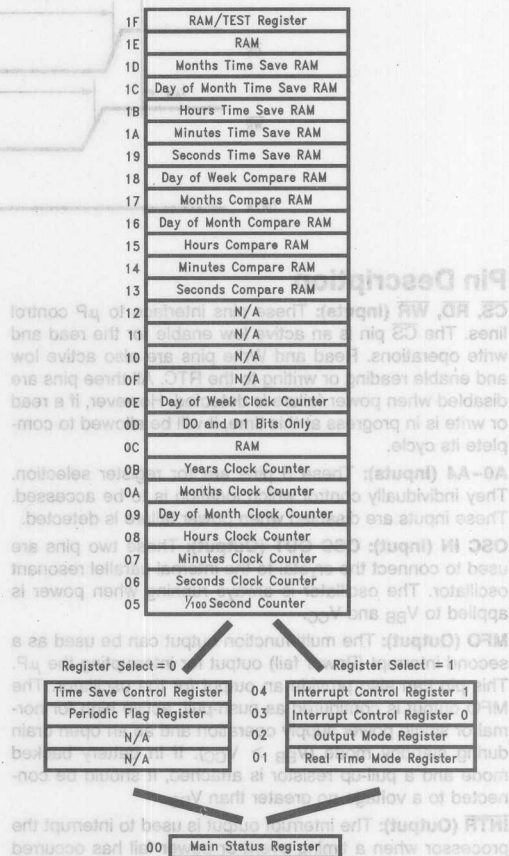

FIGURE 2. LV8573A Internal Memory Map

Functional Description (Continued)

READING THE CLOCK: VALIDATED READ

Since clocking of the counter occurs asynchronously to reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time Save Enable bit (D7) of the Time Save Control Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the TCP or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

The above method is useful when the entire clock is being corrected. If one location is being updated the clock need not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the 1/100 of a second periodic interrupt. Then wait an additional 16 μ s, and then write the data to the clock.

PRESCALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3).

FIGURE 3. Programmable Clock Prescaler Block

In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the **load capacitance** specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The RTC has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Address
Main Status Register	X	00H
Periodic Flag Register	0	03H
Interrupt Control Register 0	1	03H
Interrupt Control Register 1	1	04H
Output Mode Register	1	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all RTC interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the RTC to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system. (The Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.) Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1–D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm comparisons that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the Alarm interrupt enable bit is set (see Figure 5).

Disabling the periodic interrupts will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see Figure 5).

To clear a flag in bits D2 and D3 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Interrupts Fall Into Three Categories:

1. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
2. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.

3. The Power Fail Interrupt: Issued upon recognition of a power fail condition by the internal sensing logic. The power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The RTC then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 0 3 (BCD), the minutes compare with 1 5 (BCD) and the faster counters with 0 0 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see Figure 5. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μ P clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

Functional Description (Continued)

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μ P, but it cannot be cleared; it is cleared automatically by the RTC when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the LV8573A provides circuitry to simplify design in battery backed systems. This switches over to the back up supply, and isolates itself from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when $\overline{\text{PFAIL}}$ is low. De-bounce logic provides a $30\ \mu\text{s}$ – $63\ \mu\text{s}$ debounce time, which will prevent noise on the $\overline{\text{PFAIL}}$ pin from being interpreted as a system failure. After $30\ \mu\text{s}$ – $63\ \mu\text{s}$ the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than $30\ \mu\text{s}$ after the power fail signal is asserted, the lock-out will be forced.

The battery switch over circuitry is completely independent of the $\overline{\text{PFAIL}}$ pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the RTC will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is

disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the RTC will be configured as shown in Table II. Outputs that have a pull-up resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	$\overline{\text{PFAIL}}$ = Logic 0	Standby Mode $V_{\text{BB}} > V_{\text{CC}}$
CS, RD, WR	Locked Out	Locked Out
A0–A4	Locked Out	Locked Out
D0–D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
$\overline{\text{PFAIL}}$	Not Isolated	Not Isolated
INTR, MFO	Not Isolated	Open Drain

The Interrupt Power Fail Operation bit in the Real-Time Mode Register determines whether or not the interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as $\overline{\text{PFAIL}} = 0$. When $\overline{\text{PFAIL}} = 1$ the chip is unlocked, but only after another $30\ \mu\text{s}$ min $\rightarrow 63\ \mu\text{s}$ max debounce time. The system designer must ensure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no ex-

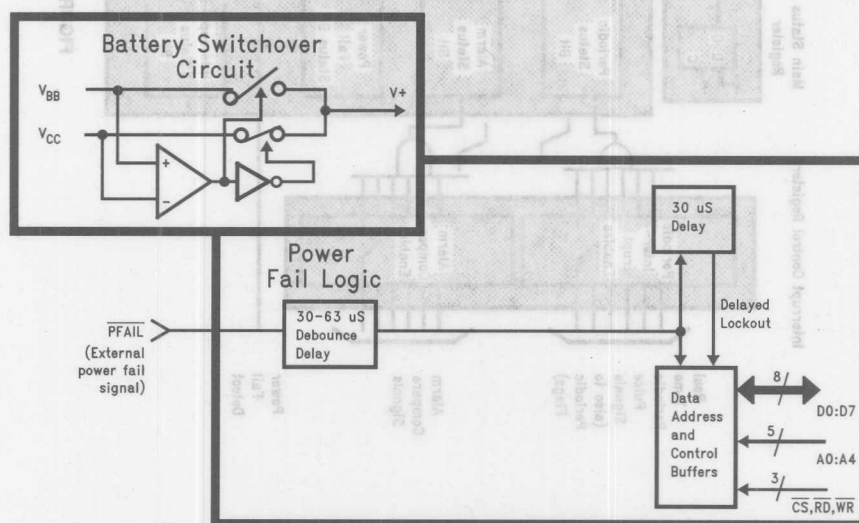

FIGURE 6. System-Battery Switchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

TL/F/11418-11

Functional Description (Continued)

ternal interrupt will be issued. Note that the linear power fail circuitry is switched off automatically when using V_{BB} in standby mode.

INITIAL POWER ON DETECT AND POWER FAIL TIME SAVE

There are two other functions provided on the LV8573A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the \overline{PFAIL} pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The LV8573A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC} . The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits.

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 28 locations at one time. An internal switching scheme provides a total of 30 locations.

The only register that does not get switched is the Main Status Register. It contains the register select bit as well as status information.

A memory map is shown in Figure 2 and register addressing in Table III. They show the name, address and page locations for the LV8573A.

TABLE III. Register/Counter/RAM Addressing for LV8573A

1F	X	RAM/Test Mode Register

Note 1: RS—Register Select (Bit D6 of Main Status Register)

The Main Status Register is always located at address 0 regardless of the register block selected.

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1–D3: These three bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μP will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PFAIL pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1 and D3 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D4, D5 and D7: General purpose RAM bits.

D6: Bit D6 controls the register block to be accessed (see memory map).

PERIODIC FLAG REGISTER

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0–D5 are read only bits, D6 and D7 are read/write.

D0–D5: These bits are set by the real time rollover events: (Time Change = 1). The bits are reset when the register is read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure might be caused are: failure of the crystal, shorting OSC IN or OSC OUT to GND or V_{CC} , removal of crystal, removal of battery when in the battery backed mode (when a "0" is written to D6), lowering the voltage at the

Time Mode Register, with the crystal oscillating.

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the LV8573A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to V_{CC} — 0.4V.

For single supply mode operation, the V_{BB} pin should be connected to GND and the PFAIL pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table III). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

TIME SAVE CONTROL REGISTER

D0–D5: General purpose RAM bits.

D6: Not Available, appears as logic 0 when read.

D7: Time Save Enable bit controls the loading of real-time-clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

D2: The count mode for the hours counter can be set to either 24 hour mode or 12 hour mode with AM/PM indicator. A one will place the clock in 12 hour mode.

D3: This bit is the master Start/Stop bit for the clock. When a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped. When the RTC is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Note that the MFO pin is configured as open drain in standby mode.

If bit D4 is set to a zero then the interrupt control register and the periodic interrupt flag will be reset when the RTC enters the standby mode ($V_{BB} > V_{CC}$). They will have to be re-configured when system (V_{CC}) power is restored.

D5-D7: General purpose RAM bits.

OUTPUT MODE REGISTER

TL/F/11418-16

D0-D6: General purpose RAM bits.

D7: This bit is used to program the signal appearing at the MFO output, as follows:

D7	MFO Output Signal
0	Power Fail Interrupt
1	Buffered Crystal Oscillator

TL/F/11418-17

D0-D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the periodic time chosen, but after the first interrupt all subsequent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin.

D6 and D7: General purpose RAM.

INTERRUPT CONTROL REGISTER 1

TL/F/11418-18

D0-D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the "always equal" state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If battery backed mode is selected, then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when a $V_{BB} > V_{CC}$. If battery backed mode is selected, then this bit is controlled by D4 of the Real Time Mode Register.

Application Hints

Suggested Initialization Procedure for LV8573A in Battery Backed Applications that use the V_{BB} Pin

1. Enter the test mode by writing a 1 to bit D7 in the Periodic Flag Register.
2. Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
3. Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1, 2, 3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.

4. Enter a software loop that does the following:

Set a 3 second(approx) software counter. The crystal oscillator may take 1 second to start.

- 4.1 Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Under normal operation, this bit can be set only if the oscillator is running. During the software loop, RAM, real time counters, output configuration, interrupt control and timer functions may be initialized.

Application Hints (Continued)

5. Test bit D6 in the Periodic Flag Register:

IF a 1, go to 4.1. If this bit remains a 1 after 3 seconds, then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 M Ω .

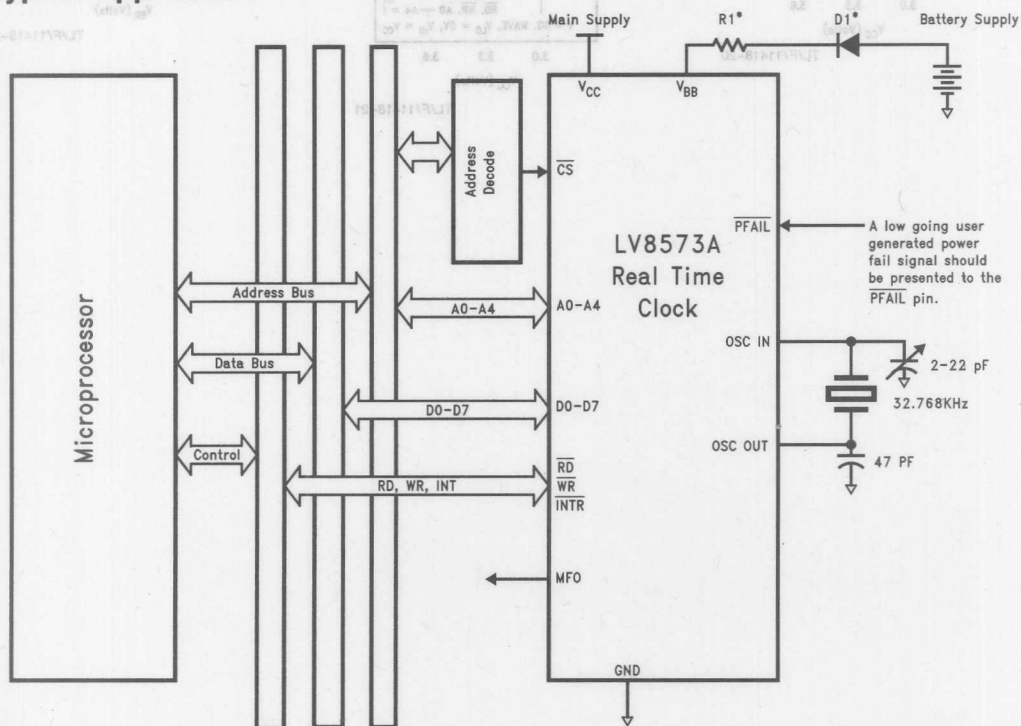

IF a 0, then the oscillator is running, go to step 7.

6. Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the OSC fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder, bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation.

The only method to ensure the chip is in the battery backed mode is to measure the waveform at the OSC OUT pin. If the battery backed mode was selected successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC} . The measurement should be made with a high impedance low capacitance probe (10 M Ω , 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.

7. Write a 1 to bit D7 of Interrupt Control Register 1. This action enables the PFAIL pin and associated circuitry.
8. Initialize the rest of the chip as needed.

Typical Application

*These components may be necessary to meet UL requirements for lithium batteries. Consult battery manufacturer.

TL/F/11418-19

DP8570A Timer Clock Peripheral (TCP)

General Description

The DP8570A is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports. The address space is organized as 2 software selectable pages of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, the Timers and their data RAM, and the Time Save RAM. Any of the RAM locations that are not being used for their intended purpose may be used as general purpose CMOS RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week, day of month and day of year counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the crystal and two capacitors. The choice of crystal frequency is program selectable.

Two independent multifunction 10 MHz 16-bit timers are provided. These timers operate in four modes. Each has its own prescaler and can select any of 8 possible clock inputs. Thus, by programming the input clocks and the timer counter values a very wide range of timing durations can be achieved. The range is from about 400 ns (4.915 MHz oscillator) to 65,535 seconds (18 hrs., 12 min.).

Power failure logic and control functions have been integrated on chip. This logic is used by the TCP to issue a power fail

interrupt, and lock out the μP interface. The time power fails may be logged into RAM automatically when $V_{BB} > V_{CC}$. Additionally, two supply pins are provided. When $V_{BB} > V_{CC}$, internal circuitry will automatically switch from the main supply to the battery supply. Status bits are provided to indicate initial application of battery power, system power, and low battery detect. (Continued)

Features

- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week and day of years counters
 - Four selectable oscillator frequencies
 - Parallel Resonant Oscillator
- Two 16-bit timers
 - 10 MHz external clock frequency
 - Programmable multi-function output
 - Flexible re-trigger facilities
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, timer and power fail interrupts
- Up to 44 bytes of CMOS RAM
- INTR/MFO/T1 pins programmable High/Low and push-pull or open drain

I_{BLK}	Battery Supply Leakage	$2.2V \leq V_{BB} \leq 4.0V$ Other Pins at GND $V_{CC} = GND$, $V_{BB} = 4.0V$ $V_{CC} = 5.5V$, $V_{BB} = 2.2V$	-5	1.5	μA μA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: For $F_{OSC} = 4.194304$ or 4.9152 MHz, V_{BB} minimum = 2.8V. In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$.

Single Supply Mode: Data retention voltage is 2.2V min.

In single Supply Mode (Power connected to V_{CC} pin) $4.5V \leq V_{CC} \leq 5.5V$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: This Specification is tested with both the timers and OSC IN driven by a signal generator. Contents of the Test Register = 00(H), the MFO pin is not configured as buffered oscillator out and MFO, T1, INTR, are configured as open drain.

Note 8: This specification is tested with both the timers off, and only OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

t_{AR}	Address Valid Prior to Read Strobe	20		ns

t_{WW}	Write Strobe Width (Note 11)	80		ns
t_{DW}	Data Valid to End of Write Strobe	50		ns
t_{WDH}	Data Hold after Write Strobe (Note 10)	3		ns
t_{WCH}	Chip Select Hold after Write Strobe	0		ns

TIMER 0/TIMER 1 TIMING

f_{TCK}	Input Frequency Range	DC	10	MHz
t_{CK}	Propagation Delay Clock to Output \square		120	ns
t_{GO}	Propagation Delay G0 to G1 to Timer Output (Note 12) \square		100	ns
t_{PGW}	Pulse Width G0 or G1 \square (Note 12)	25		ns
t_{GS}	Setup Time, G0, G1 to TCK (Note 13)	100		ns

INTERRUPT TIMING

t_{ROLL}	Clock Rollover to INTR Out is Typically 16.5 μ s			
------------	--	--	--	--

Note 9: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 10: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 11: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

Note 12: Timers in Mode 3.

Note 13: Guaranteed by design, not production tested. This limit is not used to calculate outgoing quality levels.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output Reference Levels	1.3V
TRI-STATE Reference Levels (Note 15)	Active High +0.5V Active Low –0.5V

Note 14: $C_L = 100$ pF, includes jig and scope capacitance.

Note 15: S1 = V_{CC} for active low to high impedance measurements.

S1 = GND for active high to high impedance measurements.

S1 = open for all other timing measurements.

Capacitance ($T_A = 25^\circ\text{C}$, $f = 1$ MHz)

Symbol	Parameter (Note 16)	Typ	Units
C_{IN}	Input Capacitance	5	pF
C_{OUT}	Output Capacitance	7	pF

Note 16: This parameter is not 100% tested.

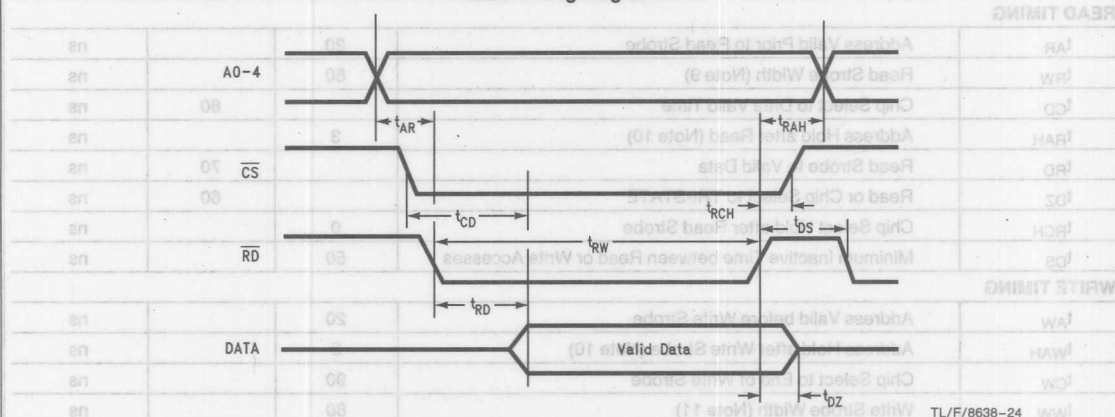

Note 17: Output rise and fall times 25 ns max (10%–90%) with 100 pF load.

Timing Waveforms

Read Timing Diagram

Write Timing Diagram

General Description (Continued)

The DP8570A's interrupt structure provides four basic types of interrupts: Periodic, Alarm/Compare, Timer, and Power Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

One dedicated general purpose interrupt output is provided. A second interrupt output is available on the Multiple Function Output (MFO) pin. Each of these may be selected to generate an interrupt from any source. Additionally, the MFO pin may be programmed to be either as oscillator output or Timer 0's output.

Pin Description

CS, RD, WR (Inputs): These pins interface to μ P control lines. The $\overline{\text{CS}}$ pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the TCP. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} , and the correct crystal select bits in the Real Time Mode Register have been set.

MFO (Output): The multi-function output can be used as a second interrupt output for interrupting the μ P. This pin can also provide an output for the oscillator or the internal Timer 0. The MFO output can be programmed active high or low, open drain or push-pull. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . This pin is configured open drain during battery operation ($V_{BB} > V_{CC}$).

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The INTR output can be programmed active high or low, push-pull or open drain. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . This pin is configured open drain during battery operation ($V_{BB} > V_{CC}$). The output is a DC voltage level. To clear the INTR, write a 1 to the appropriate bit(s) in the Main Status Register.

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μ P's data bus and are used to read from and write to the TCP. When the $\overline{\text{PFAIL}}$ pin goes low and a write is not in progress, these pins are at TRI-STATE.

PFAIL (Input): In battery backed mode, this pin can have a digital signal applied to it via some external power detection logic. When $\overline{\text{PFAIL}} = \text{logic 0}$ the TCP goes into a lockout mode, in a minimum of 30 μ s or a maximum of 63 μ s unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

V_{BB} (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be

used then this pin must be tied to ground, the TCP programmed for single power supply only, and power applied to the V_{CC} pin.

TCK, G1, G0, (Inputs), T1 (Output): TCK is the clock input to both timers when they have an external clock selected. In modes 0, 1, and 2, G0 and G1 are active low enable inputs for timers 0 and 1 respectively. In mode 3, G0 and G1 are positive edge triggers to the timers. T1 is dedicated to the timer 1 output. The T1 output can be programmed active high or low, push-pull or open drain. Timer 0 output is available through MFO pin if desired. If in battery backed mode and a pull-up resistor is attached to T1, it should be connected to a voltage no greater than V_{BB} . The T1 pin is configured open drain during battery operation ($V_{BB} > V_{CC}$).

V_{CC} : This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

Functional Description

The DP8570A contains a fast access real time clock, two 10 MHz 16-bit timers, interrupt control logic, power fail detect logic, and CMOS RAM. All functions of the TCP are controlled by a set of nine registers. A simplified block diagram that shows the major functional blocks is given in Figure 1.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management
6. Timers

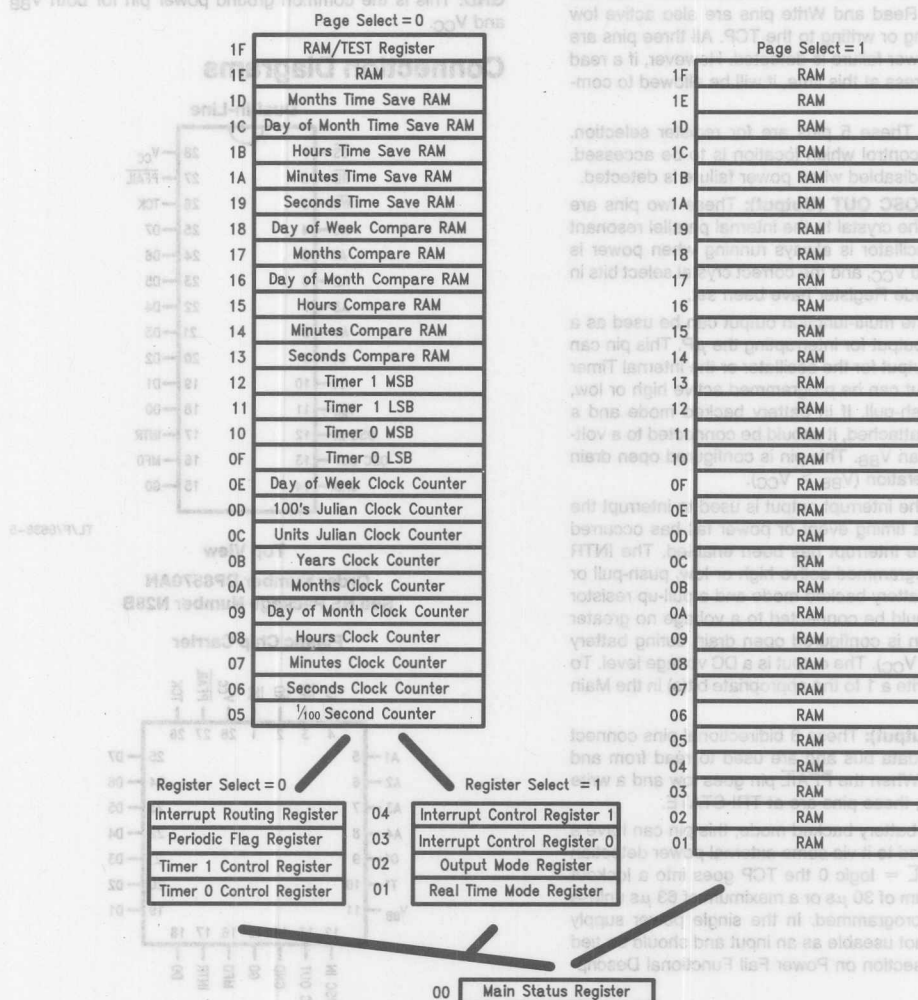

FIGURE 2. DP8570A Internal Memory Map

Functional Description (Continued)

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of 1 M Ω . The user should be aware that the control registers will contain random data. The first task to be carried out in an initialization routine is to start the oscillator by writing to the crystal select bits in the Real Time Mode Register. If the DP8570A is configured for single supply mode, an extra 50 μ A may be consumed until the crystal select bits are programmed. The user should also ensure that the TCP is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 10 bytes of counters, which count from 1/100 of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, day of year, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Also note that the day of year counter is 12 bits long and occupies two addresses. Upon initial application of power the counters will contain random information.

READING THE CLOCK: VALIDATED READ

Since clocking of the counter occurs asynchronously to reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time

Save Enable bit (D7) of the Interrupt Routing Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the TCP or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

The above method is useful when the entire clock is being corrected. If one location is being updated the clock need not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the 1/100 of a second periodic interrupt. Then wait an additional 16 μ s, and then write the data to the clock.

PRESCALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3). The crystal frequency that can be selected are: 32 kHz, 32.768 kHz, 4.9152 MHz, and 4.194304 MHz.

Once 32 kHz is generated it feeds both timers and the clock. The clock and timer prescalers can be independently enabled by controlling the timer or clock Start/Stop bits.

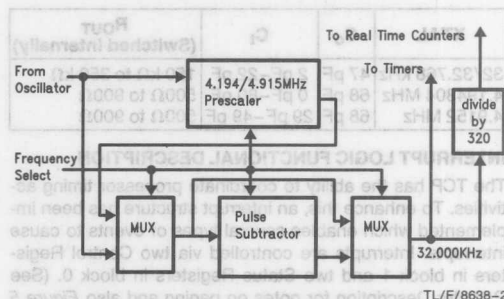

FIGURE 3. Programmable Clock Prescaler Block

Functional Description (Continued)

The oscillator is programmed via the Real Time Mode Register to operate at various frequencies. The crystal oscillator is designed to offer optimum performance at each frequency. Thus, at 32.768 kHz the oscillator is configured as a low frequency and low power oscillator. At the higher frequencies the oscillator inverter is reconfigured. In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the load capacitance specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

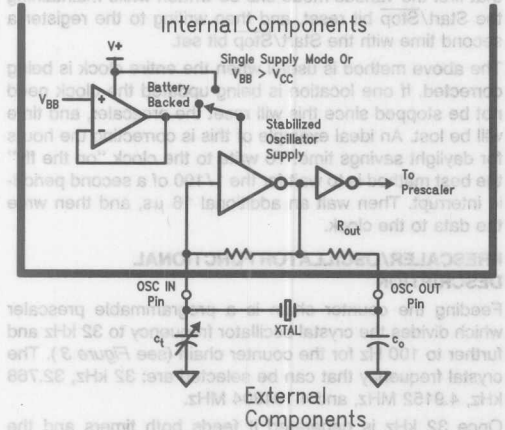

FIGURE 4. Oscillator Circuit Diagram

XTAL	C ₀	C _t	R _{OUT} (Switched Internally)
32/32.768 kHz	47 pF	2 pF–22 pF	150 kΩ to 350 kΩ
4.194304 MHz	68 pF	0 pF–80 pF	500Ω to 900Ω
4.9152 MHz	68 pF	29 pF–49 pF	500Ω to 900Ω

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The TCP has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and also Figure 5 and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1. Any of the interrupts can be routed to either the INTR pin or the MFO pin, depending on how the Interrupt Routing register is programmed. This, for example, enables the user to dedicate the MFO as a non-maskable interrupt pin to the CPU for power failure detection and enable all other interrupts to appear on the INTR pin. The polarity of the active interrupt can be programmed in the Output Mode Register for either active high or low, and open drain or push pull outputs.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Page Select	Address
Main Status Register	X	X	00H
Periodic Flag Register	0	0	03H
Interrupt Routing Register	0	0	04H
Interrupt Control Register 0	1	0	03H
Interrupt Control Register 1	1	0	04H
Output Mode Register	1	0	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all TCP interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the TCP to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system.

Note that the Interrupt Status Flag will only monitor the state of the MFO output if it has been configured as an interrupt output (see Output Mode Register description). This is true, regardless of the state of the Interrupt Routing Register. Thus the Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.

Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1–D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm or Timer interrupts that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the appropriate Alarm or Timer interrupt enable bits are set (see Figure 5).

Disabling the periodic bits will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see Figure 5).

To clear a flag in bits D2–D5 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Functional Description (Continued)

Interrupts Fall Into Four Categories:

1. The Timer Interrupts: For description see Timer Section.
2. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
3. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.
4. The Power Fail Interrupt: Issued upon recognition of a power fail condition by the internal sensing logic. The power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The TCP then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 0 3 (BCD), the minutes compare with 1 5 (BCD) and the faster counters with 0 0 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see Figure 5. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register. The Periodic Route bit in the Interrupt Routing Register is used to route the periodic interrupt events to either the INTR output or the MFO output.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μ P clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μ P, but it cannot be cleared; it is cleared automatically by the TCP when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set.

The Power Fail Route bit determines which output the interrupt will appear on. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the DP8570A provides circuitry to simplify design in battery backed systems. This circuitry switches over to the back up supply, and isolates the DP8570A from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when PFAIL is low. Debounce logic provides a 30 μ s–63 μ s debounce time, which will prevent noise on the PFAIL pin from being interpreted as a system failure. After 30 μ s–63 μ s the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

Functional Description (Continued)

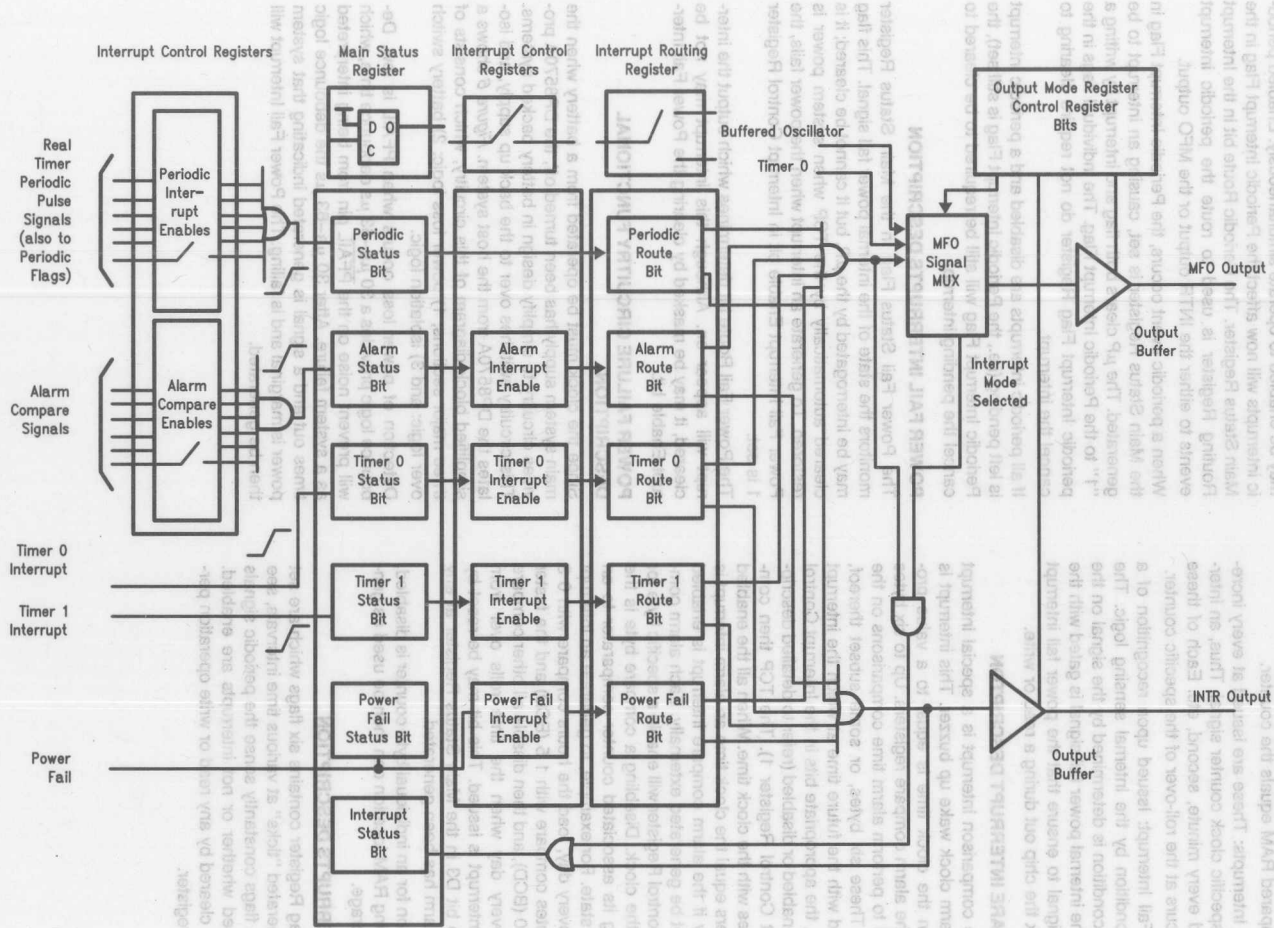

FIGURE 5. Interrupt Control Logic Overview

Functional Description (Continued)

Functional Description (Continued)

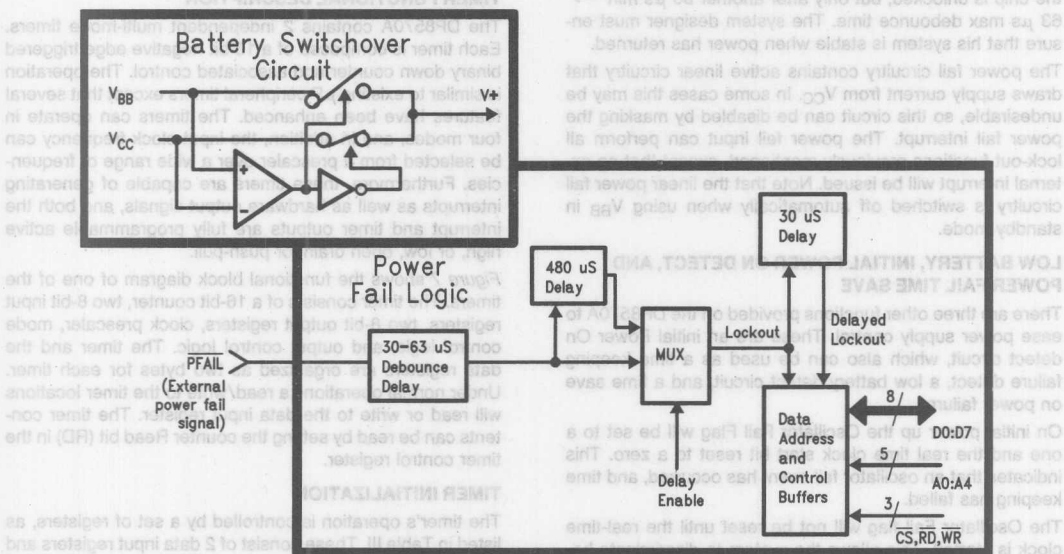

FIGURE 6. System-Battery Switchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

The user may choose to have this power failed signal lock-out the TCP's data bus within 30 μs min/63 μs max or to delay the lock-out to enable μP access after power failure is detected. This delay is enabled by setting the delay enable bit in the Routing Register. Also, if the lock-out delay was not enabled the TCP will disconnect itself from the bus within 30 μs min \rightarrow 63 μs max. If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than 30 μs after the power fail signal is asserted, the lock-out will be forced. If a lock-out delay is enabled, the DP8570A will remain active for 480 μs after power fail is detected. This will enable the μP to perform last minute bookkeeping before total system collapse. When the host CPU is finished accessing the TCP it may force the bus lock-out before 480 μs has elapsed by resetting the delay enable bit.

The battery switch over circuitry is completely independent of the PFAIL pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the TCP will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the TCP will be configured as shown in Table II. Outputs that have a pull-up resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	PFAIL = Logic 0	Standby Mode $V_{BB} > V_{CC}$
CS, RD, WR	Locked Out	Locked Out
A0-A4	Locked Out	Locked Out
D0-D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
TCK, G0, G1	Not Isolated	Locked Out
PFAIL	Not Isolated	Not Isolated
INTR, MFO T1	Not Isolated	Open Drain

The Timer and Interrupt Power Fail Operation bits in the Real-Time Mode Register determine whether or not the timers and interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as PFAIL = 0. When PFAIL = 1

Functional Description (Continued)

the chip is unlocked, but only after another 30 μ s min \rightarrow 63 μ s max debounce time. The system designer must ensure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no external interrupt will be issued. Note that the linear power fail circuitry is switched off automatically when using V_{BB} in standby mode.

LOW BATTERY, INITIAL POWER ON DETECT, AND POWER FAIL TIME SAVE

There are three other functions provided on the DP8570A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, a low battery detect circuit, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

Another status bit is the low battery detect. This bit is set only when the clock is operating under the V_{CC} pin, and when the battery voltage is determined to be less than 2.1V (typical). When the power fail interrupt enable bit is low, it disables the power fail circuit and will also shut off the low battery voltage detection circuit as well.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the PFAIL pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The DP8570A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC} and PFAIL pins. The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits. Until the crystal select bits are initialized, the DP8570A may consume about 50 μ A due to arbitrary oscillator selection at power on.

(This extra 50 μ A is not consumed if the battery backed mode is selected).

TIMER FUNCTIONAL DESCRIPTION

The DP8570A contains 2 independent multi-mode timers. Each timer is composed of a 16-bit negative edge triggered binary down counter and associated control. The operation is similar to existing μ P peripheral timers except that several features have been enhanced. The timers can operate in four modes, and in addition, the input clock frequency can be selected from a prescaler over a wide range of frequencies. Furthermore, these timers are capable of generating interrupts as well as hardware output signals, and both the interrupt and timer outputs are fully programmable active high, or low, open drain, or push-pull.

Figure 7 shows the functional block diagram of one of the timers. The timer consists of a 16-bit counter, two 8-bit input registers, two 8-bit output registers, clock prescaler, mode control logic, and output control logic. The timer and the data registers are organized as two bytes for each timer. Under normal operations a read/write to the timer locations will read or write to the data input register. The timer contents can be read by setting the counter Read bit (RD) in the timer control register.

TIMER INITIALIZATION

The timer's operation is controlled by a set of registers, as listed in Table III. These consist of 2 data input registers and one control register per timer. The data input registers contain the timers count down value. The Timer Control Register is used to set up the mode of operation and the input clock rate. The timer related interrupts can be controlled by programming the Interrupt Routing Register and Interrupt Control Register 0. The timer outputs are configured by the Output Mode Register.

TABLE III. Timer Associated Registers

Register Name	Register Select	Page Select	Address
Timer 0 Data MSB	X	0	10H
Timer 0 Data LSB	X	0	0FH
Timer 0 Control Register	0	0	01H
Timer 1 Data MSB	X	0	12H
Timer 1 Data LSB	X	0	11H
Timer 1 Control Register	0	0	02H
Interrupt Routing Register	0	0	04H
Interrupt Control Reg. 0	1	0	03H
Output Mode Register	1	0	02H

All these registers must be initialized prior to starting the timer(s). The Timer Control Register should first be set to select the timer mode with the timer start/stop bit reset. Then when the timer is to be started the control register should be rewritten identically but with the start/stop bit set.

TIMER OPERATION

Each timer is capable of operation in one of four modes. As mentioned, these modes are programmed in each timer's Control Register which is described later. All four modes operate in a similar manner. They operate on the two 8-bit data words stored into the Data Input Register. At the beginning of a counting cycle the 2 bytes are loaded into the timer and the timer commences counting down towards zero. The exact action taken when zero is reached depends on the mode selected, but in general, the timer output will change state, and an interrupt will be generated if the timer interrupts are unmasked.

Functional Description (Continued)

INPUT CLOCK SELECTION

The input frequency to the timers may be selected. Each timer has a prescaler that gives a wide selection of clocking rates. In addition, the DP8570A has a single external clock input pin that can be selected for either of the timers. Table IV shows the range of programmable clocks available and the corresponding setting in the Timer Control Register.

TABLE IV. Programmable Timer Input Clocks

C2	C1	C0	Selected Clock
0	0	0	External
0	0	1	Crystal Oscillator
0	1	0	(Crystal Oscillator)/4
0	1	1	93.5 μ s (10.7 kHz)
1	0	0	1 ms (1 kHz)
1	0	1	10 ms (100 Hz)
1	1	0	1/10 Second (10 Hz)
1	1	1	1 Second (1 Hz)

Note that the second and third selections are not fixed frequencies, but depend on the crystal oscillator frequency chosen.

Since the input clock frequencies are usually running asynchronously to the timer Start/Stop control bit, a 1-clock cycle error may result. This error results when the Start/Stop occurs just after the clock edge (max error). To minimize this error on all clocks an independent prescaler is used for each timer and is designed so that its Start/Stop error is less than 1 clock cycle.

The count hold/gate bit in the Timer Control Register and the external enable pins, G0/G1, can be used to suspend the timer operation in modes 0, 1, and 2 (in mode 3 it is the trigger input). The external pin and the register bit are OR'ed

together, so that when either is high the timers are suspended. Suspending the timer causes the same synchronization error that starting the timer does. The range of errors is specified in Table V.

TABLE V. Maximum Synchronization Errors

Clock Selected	Error
External	+ Ext. Clock Period
Crystal	+ 1 Crystal Clock Period
Crystal/4	+ 1 Crystal Clock Period
10.7 kHz	+ 32 μ s
1 kHz	+ 32 μ s
100 Hz	+ 32 μ s
10 Hz	+ 32 μ s
1 Hz	+ 32 μ s

MODES OF OPERATION

Bits M0 and M1 in the Timer Control Registers are used to specify the modes of operation. The mode selection is described in Table VI.

TABLE VI. Programmable Timer Modes of Operation

M1	M0	Function	Modes
0	0	Single Pulse Generator	Mode 0
0	1	Rate Generator, Pulse Output	Mode 1
1	0	Square Wave Output	Mode 2
1	1	Retriggerable One Shot	Mode 3

MODE 0: SINGLE PULSE GENERATOR

When the timer is in this mode the output will be initially low if the Timer Start/Stop bit is low (stopped). When this mode is initiated the timer output will go high on the next falling edge of the prescaler's input clock, the contents

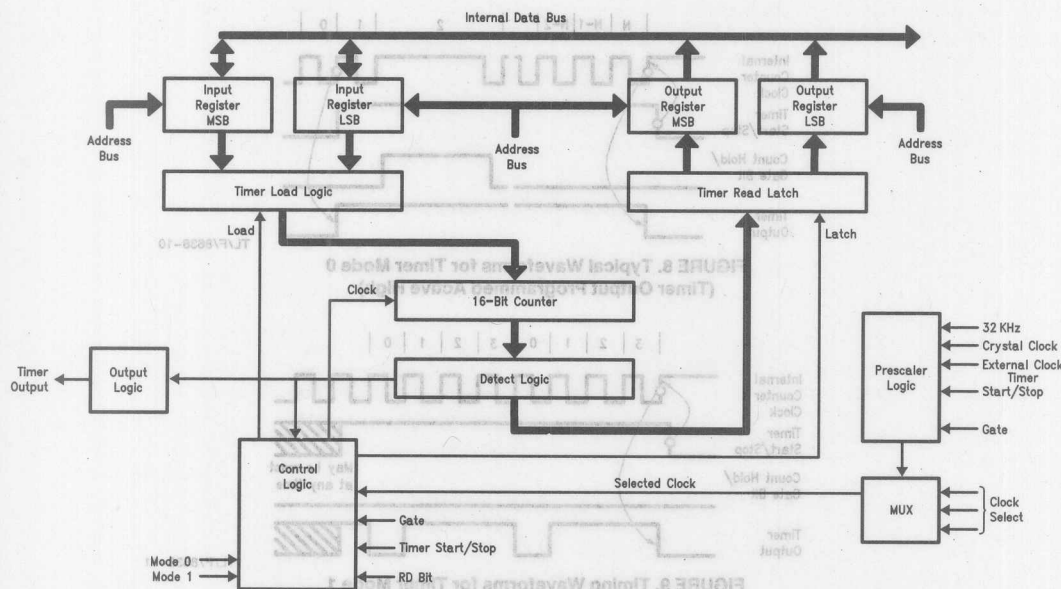

FIGURE 7. DP8570A Timer Block Diagram

TL/F/8638-9

Functional Description (Continued)

of the input data registers are loaded into the timer. The output will stay high until the counter reaches zero. At zero the output is reset. The result is an output pulse whose duration is equal to the input clock period times the count value (N) loaded into the input data register. This is shown in Figure 8.

$$\text{Pulse Width} = \text{Clock Period} \times N$$

An interrupt is generated when the zero count is reached. This can be used for one-time interrupts that are set to occur a certain amount of time in the future. In this mode the Timer Start/Stop bit (TSS) is automatically reset upon zero detection. This removes the need to reset TSS before starting another operation.

The count down operation may be temporarily suspended either under software control by setting the Count Hold/Gate bit in the timer register high, or in hardware by setting the G0 or G1 pin high.

The above discussion assumes that the timer outputs were programmed to be non-inverting outputs (active high). If the polarity of the output waveform is wrong for the application the polarity can be reversed by configuring the Output Mode Register. The drive configuration can also be programmed to be push pull or open drain.

MODE 1: RATE GENERATOR

When operating in this mode the timer will operate continuously. Before the timer is started its output is low. When the timer is started the input data register contents are loaded into the counter on the negative clock edge and the output is set high (again assuming the Output Mode Register is programmed active high). The timer will then count down to zero. Once the zero count is reached the output goes low

for one clock period of the timer clock. Then on the next clock the counter is reloaded automatically and the count-down repeats itself. The output, shown in Figure 9, is a waveform whose pulse width and period is determined by N, the input register value, and the input clock period:

$$\text{Period} = (N + 1) (\text{Clock Period})$$

$$\text{Pulse Width} = \text{Clock Period}$$

The G0 or G1 pin and the count hold/gate bit can be used to suspend the appropriate timer countdown when either is high. Again, the output polarity is controllable as in mode 0. If enabled, an interrupt is generated whenever the zero count is reached. This can be used to generate a periodic interrupt.

MODE 2: SQUARE WAVE GENERATOR

This mode is also cyclic but in this case a square wave rather than a pulse is generated. The output square wave period is determined by the value loaded into the timer input register. This period and the duty cycle are:

$$\text{Period} = 2(N + 1) (\text{Clock Period}) \quad \text{Duty Cycle} = 0.5$$

When the timer is stopped the output will be low, and when the Start/Stop bit is set high the timer's counter will be loaded on the next clock falling transition and the output will be set high.

The output will be toggled after the zero count is detected and the counter will then be reloaded, and the cycle will continue. Thus, every $N + 1$ counts the output gets toggled, as shown in Figure 10. Like the other modes the timer operation can be suspended either by software setting the count hold/gate bit (CHG) in the Timer Control Register or by using the gate pins. An interrupt will be generated every falling edge of the timer output, if enabled.

FIGURE 8. Typical Waveforms for Timer Mode 0 (Timer Output Programmed Active High)

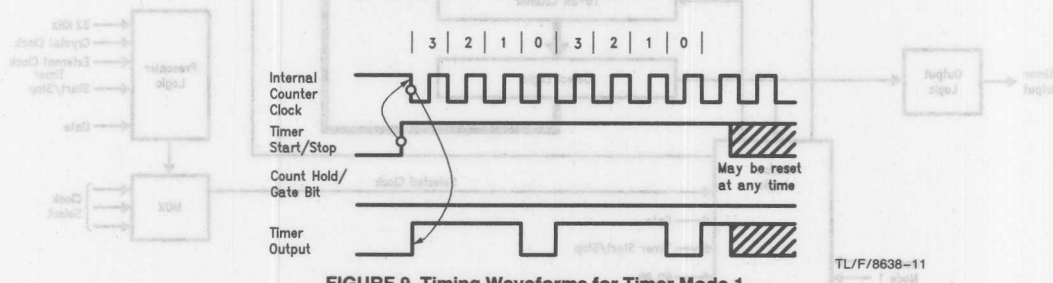

FIGURE 9. Timing Waveforms for Timer Mode 1 (Timer Output Programmed Active High)

Functional Description (Continued)

FIGURE 10. Timing Waveforms for Timer Mode 2
(Timer Output Programmed Active High)

MODE 3: RETRIGGERABLE ONE SHOT

This mode is different from the previous three modes in that this is the only mode which uses the external gate to trigger the output. Once the timer Start/Stop bit is set the output stays inactive, and nothing happens until a positive transition is received on the G1 or G0 pins, or the Count Hold/Gate (CHG) bit is set in the timer control register. When a transition occurs the one shot output is set active immediately; the counter is loaded with the value in the input register on the next transition of the input clock and the countdown begins. If a retrigger occurs, regardless of the current counter value, the counters will be reloaded with the value in the input register and the counter will be restarted without changing the output state. See Figure 11. A trigger count can occur at any time during the count cycle and can be a hardware or software signal (G0, G1 or CHG). In this mode the timer will output a single pulse whose width is determined by the value in the input data register (N) and the input clock period.

$$\text{Pulse Width} = \text{Clock Period} \times N$$

Before entering mode 3, if a spurious edge has occurred on G0/G1 or the CHG bit is set to logic 1, then a pulse will appear at MFO or T1 or INTR output pin when the timer is started. To ensure this does not happen, do the following steps before entering mode 3: Configure the timer for mode 0, load a count of zero, then start the timer.

The timer will generate an interrupt only when it reaches a count of zero. This timer mode is useful for continuous "watch dog" timing, line frequency power failure detection, etc.

READING THE TIMERS

National has discovered that some users may encounter unacceptable error rates for their applications when reading the timers on the fly asynchronously. When doing asynchronous reads of the timers, an error may occur. The error is that a successive read may be larger than the previous

read. Experimental results indicate that the typical error rate is approximately one per 29,000 under the following conditions:

Timer clock frequency of 5 MHz.

Computer: 386/33 MHz PC/AT

Program: Microsoft "C" 6.0, reading and saving timer contents in a continuous loop.

Those users who find the error rate unacceptable may reduce the problem effectively to zero by employing a hardware work-around that synchronizes the writing of the read bit to the timer control register with respect to the decrementing clock. Refer to Figure 1 in Appendix A, for a suggested hardware work-around.

A software work-around can reduce the errors but not as substantial as a hardware work-around. Software work-arounds are based on observations that the read following a bad read appeared to be valid.

This problem concerns statistical probability and is similar to metastability issues. For more information on metastability, refer to 1991 IEEE transactions on Custom Integrated Circuits Conference, paper by T.J. Gabara of AT&T Bell Laboratories, page 29.4.1.

Normally reading the timer data register addresses, 0FH and 10H for Timer 0 and 11H and 12H for Timer 1 will result in reading the input data register which contains the preset value for the timers.

To read the contents of a timer, the μP first sets the timer read bit in the appropriate Timer Control Register high. This will cause the counters contents to be latched to 2-bit-8-bit output registers, and will enable these registers to be read if the μP reads the timers input data register addresses. On reading the LSB byte the timer read bit is internally reset and subsequent reads of the timer locations will return the input register values.

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 32 locations at one time. An internal switching scheme provides a total of 67 locations.

This complete address space is organized into two pages. Page 0 contains two blocks of control registers, timers, real time clock counters, and special purpose RAM, while page 1 contains general purpose RAM. Using two blocks enables the 9 control registers to be mapped into 5 locations. The only register that does not get switched is the Main Status Register. It contains the page select bit and the register select bit as well as status information.

A memory map is shown in Figure 2 and register addressing in Table VII. They show the name, address and page locations for the DP8570A.

Note 2: RS—Register Select (Bit D6 of Main Status Register)

Note 3: The LSB counters count 0-99 until the hundreds of days counter reaches 3. Then the LSB counters count to 65 or 66 (if a leap year). The rollover is from 365/366 to 1.

MAIN STATUS REGISTER

TL/F/8638-14

The Main Status Register is always located at address 0 regardless of the register block or the page selected.

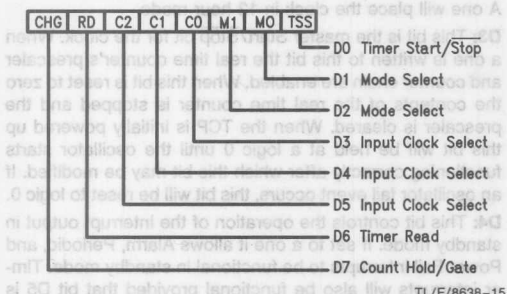

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3-D5 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1-D5: These five bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μP will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PFAIL pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1, D3-D5 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D6 and D7: These bits are Read/Write bits that control which register block or RAM page is to be selected. Bit D6 controls the register block to be accessed (see memory map). The memory map of the clock is further divided into two memory pages. One page is the registers, clock and timers, and the second page contains 31 bytes of general purpose RAM. The page selection is determined by bit D7.

Functional Description (Continued)

TIMER 0 AND 1 CONTROL REGISTER

These registers control the operation of the timers. Each timer has its own register.

D0: This bit will Start (1) or Stop (0) the timer. When the timer is stopped the timer's prescaler and counter are reset, and the timer will restart from the beginning when started again. In mode 0 on time out the TSS bit is internally reset.

D1 and D2: These control the count mode of the timers. See Table VI.

D3–D5: These bits control which clock signal is applied to the timer's counter input. There is one external clock input pin (TCK) and either (or both) timer(s) can be selected to run off this pin: refer to Table IV for details.

D6: This is the read bit. If a one is written into this location it will cause the contents of the timer to be latched into a holding register, which can be read by the μ P at any time. Reading the least significant byte of the timer will reset the RD bit. The timer read cycle can be aborted by writing RD to zero.

D7: The CHG bit has two mode dependent functions. In modes 0 through 2 writing a one to this bit will suspend the timer operation (without resetting the timer prescaler). However, in mode 3 this bit is used to trigger or re-trigger the count sequence as with the gate pins. If retriggering is desired using the CHG bit, it is not necessary to write a zero to this location prior to the re-trigger. The action of further writing a one to this bit will re-trigger the count.

PERIODIC FLAG REGISTER

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0–D5 are read only bits, D6 and D7 are read/write.

D0–D5: These bits are set by the real time rollover events: (Time Change = 1). The bits are reset when the register is read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure may be caused are: failure of the crystal; shorting OSC IN or OSC OUT to GND or V_{CC} ; removal of crystal; removal of battery when in the battery backed mode (when a '0' is written to D6); lowering the voltage at the V_{BB} pin to a value less than 2.2V when in the battery backed mode. Bit D6 is automatically set to 1 on initial power-up or an oscillator fail event. The oscillator fail flag is reset by writing a one to the clock start/stop bit in the Real Time Mode Register, with the crystal oscillating.

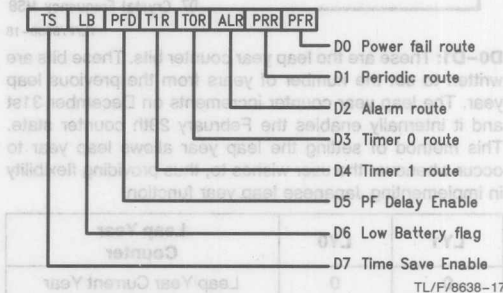

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the DP8570A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to $V_{CC} - 0.4V$.

For single supply mode operation, the V_{BB} pin should be connected to GND and the PFAIL pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table VII). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

INTERRUPT ROUTING REGISTER

D0–D4: The lower 5 bits of this register are associated with the main interrupt sources created by this chip. The purpose of this register is to route the interrupts to either the MFO (multi-function pin), or to the main interrupt pin. When any bit is set the associated interrupt signal will be sent to the MFO pin, and when zero it will be sent to the INTR pin.

Functional Description (Continued)

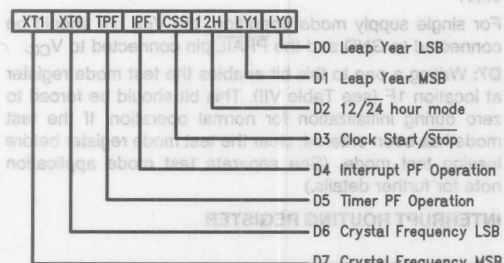

D5: The Delay Enable bit is used when a power fail occurs. If this bit is set, a 480 μ s delay is generated internally before the μ P interface is locked out. This will enable the μ P to access the registers for up to 480 μ s after it receives a power fail interrupt. After a power failure is detected but prior to the 480 μ s delay timing out, the host μ P may force immediate lock out by resetting the Delay Enable bit. Note if this bit is a 0 when power fails then after a delay of 30 μ s min/63 μ s max the μ P cannot read the chip.

D6: This read only bit is set and reset by the voltage at the V_{BB} pin. It can be used by the μ P to determine whether the battery voltage at the V_{BB} pin is getting too low. A comparator monitors the battery and when the voltage is lower than 2.1V (typical) this bit is set. The power fail interrupt must be enabled to check for a low battery voltage.

D7: Time Save Enable bit controls the loading of real-time-clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

TL/F/8638-18

D0-D1: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

D2: The count mode for the hours counter can be set to either 24 hour mode or 12 hour mode with AM/PM indicator. A one will place the clock in 12 hour mode.

D3: This bit is the master Start/Stop bit for the clock. When a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped and the prescaler is cleared. When the TCP is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Timer interrupts will also be functional provided that bit D5 is also set. Note that the MFO and INTR pins are configured as open drain in standby mode.

If bit D4 is set to a zero then interrupt control register 0 and bits D6 and D7 of interrupt control register 1 will be reset when the TCP enters the standby mode ($V_{BB} > V_{CC}$). They will have to be re-configured when system (V_{CC}) power is restored.

D5: This bit controls the operation of the timers in standby mode. If set to a one the timers will continue to function when the TCP is in standby mode. The input pins TCK, G0, G1 are locked out in standby mode, and cannot be used. Therefore external control of the timers is not possible in standby mode. Note also that MFO and T1 pins are automatically reconfigured open drain during standby.

D6 and D7: These two bits select the crystal clock frequency as per the following table:

XT1	XT0	Crystal Frequency
0	0	32.768 kHz
0	1	4.194304 MHz
1	0	4.9152 MHz
1	1	32.000 kHz

All bits are Read/Write, and any mode written into this register can be determined by reading the register. On initial power up these bits are random.

OUTPUT MODE REGISTER

TL/F/8638-19

Functional Description (Continued)

D0: This bit, when set to a one makes the T1 (timer 1) output pin active high, and when set to a zero, it makes this pin active low.

D1: This bit controls whether the T1 pin is an open drain or push-pull output. A one indicates push-pull.

D2: This bit, when set to a one makes the INTR output pin active high, and when set to a zero, it makes this pin active low.

D3: This bit controls whether the INTR pin is an open drain or push-pull output. A one indicates push-pull.

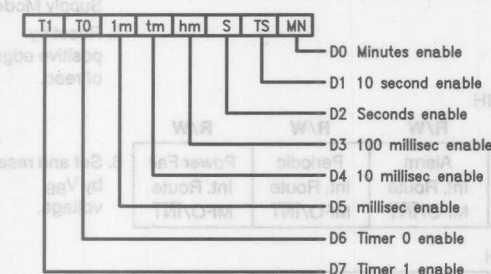

D4: This bit, when set to a one makes the MFO output pin active high, and when set to a zero, it makes this pin active low.

D5: This bit controls whether the MFO pin is an open drain or push-pull output. A one indicates push-pull.

D6 and D7: These bits are used to program the signal appearing at the MFO output, as follows:

D7	D6	MFO Output Signal
0	0	2nd Interrupt
0	1	Timer 0 Waveform
1	X	Buffered Crystal Oscillator

INTERRUPT CONTROL REGISTER 0

If battery backed mode is selected and the DP8570A is in standby ($V_{BB} > V_{CC}$), then all bits are controlled by D4 of the Real Time Mode Register.

D0–D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the

periodic time chosen, but after the first interrupt all subsequent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin.

D6 and D7: These are individual timer enable bits. A one written to these bits enable the timers to generate interrupts to the μP .

INTERRUPT CONTROL REGISTER 1

D0–D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the "always equal" state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If battery backed mode is selected and the DP8570A is in standby ($V_{BB} > V_{CC}$), then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when $PF_{FAIL} = 0$. If battery backed mode is selected and the DP8570A is in standby ($V_{BB} > V_{CC}$), then this bit is controlled by D4 of the Real Time Mode Register.

This bit also enables the low battery detection analog circuitry.

If the user wishes to mask the power fail interrupt, but utilize the analog circuitry, this bit should be enabled, and the Routing Register can be used to route the interrupt to the MFO pin. The MFO pin can then be left open or configured as the Timer 0 or buffered oscillator output.

Application Hints

Suggested Initialization Procedure for DP8570A in battery backed applications that use the V_{BB} pin

1. Enter the test mode by writing a 1 to bit D7 in the Periodic Flag Register.
2. Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
3. Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1, 2, 3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.
4. After power on (V_{CC} and V_{BB} powered), select the correct crystal frequency bits (D7, D6 in the Real Time Mode Register) as shown in Table I.

TABLE I

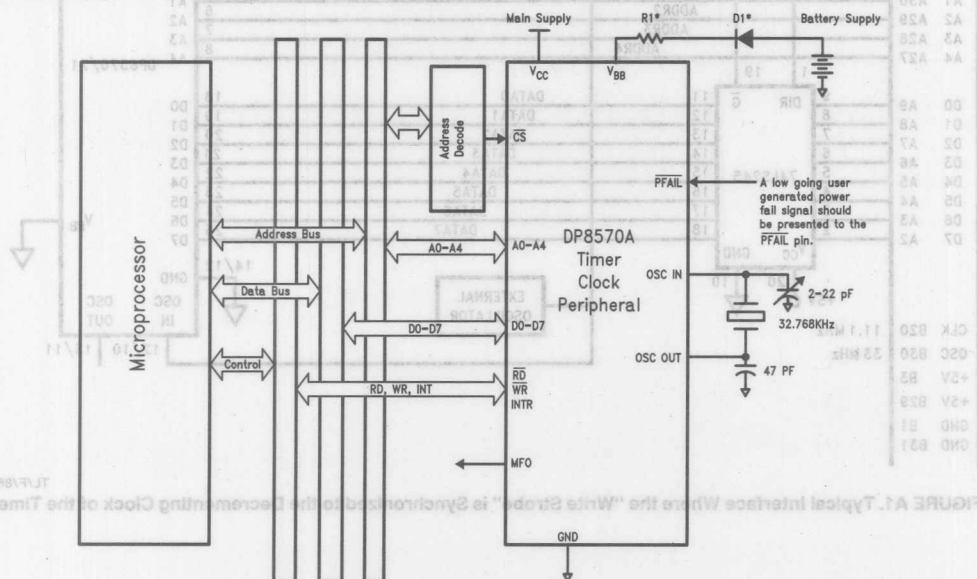

Frequency	D7	D6
32.768 kHz	0	0
4.194304 MHz	0	1
4.9152 MHz	1	0
32.0 kHz	1	1

5. Enter a software loop that does the following:
Set a 3 second (approx.) software counter. The crystal oscillator may take 1 second to start.
5.1 Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Make sure the crystal select bits remain the same as in step 1. Under normal operation, this bit can be set only if the oscillator is

running. During the software loop, RAM, real time counters, output configuration, interrupt control and timer functions may be initialized.

6. Test bit D6 in the Periodic Flag Register:
IF a 1, go to 5.1. If this bit remains a 1 after 3 seconds, then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 MΩ.
IF a 0, then the oscillator is running, go to step 7.
7. Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the osc fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder, Bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation. The only method to ensure the chip is in the battery backed mode is to measure the waveform at the OSC OUT pin. If the battery backed mode was selected successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC}. The measurement should be made with a high impedance low capacitance probe (10 MΩ, 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.
8. Write a 1 to bit D7 of Interrupt Control Register 1. This action enables the PFAIL pin and associated circuitry.
9. Write a 1 to bit D4 of the Real Time Mode Register. This action ensures that bit D7 of Interrupt Control Register 1 remains a 1 when V_{BB} > V_{CC} (Standby Mode).
10. Initialize the rest of the chip as needed.

Typical Application

*These components may be necessary to meet UL requirements for lithium batteries. Consult battery manufacturer.

DP8571A Timer Clock Peripheral (TCP)

General Description

The DP8571A is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports. The address space is organized as 2 software selectable pages of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, the Timers and their data RAM, and the Time Save RAM. Any of the RAM locations that are not being used for their intended purpose may be used as general purpose CMOS RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week, day of month and day of year counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the crystal and two capacitors. The choice of crystal frequency is program selectable.

Two independent multifunction 10 MHz 16-bit timers are provided. These timers operate in four modes. Each has its own prescaler and can select any of 7 possible clock inputs. Thus, by programming the input clocks and the timer counter values a very wide range of timing durations can be achieved. The range is from about 400 ns (4.915 MHz oscillator) to 65,535 seconds (18 hrs., 12 min.).

Power failure logic and control functions have been integrated on chip. This logic is used by the TCP to issue a power fail

interrupt, and lock out the μP interface. The time power fails may be logged into RAM automatically when $V_{BB} > V_{CC}$. Additionally, two supply pins are provided. When $V_{BB} > V_{CC}$, internal circuitry will automatically switch from the main supply to the battery supply. Status bits are provided to indicate initial application of battery power, system power, and low battery detect.

(Continued)

Features

- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week and day of years counters
 - Four selectable oscillator frequencies
 - Parallel resonant oscillator
- Two 16-bit timers
 - 10 MHz external clock frequency
 - Programmable multi-function output
 - Flexible re-trigger facilities
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, timer and power fail interrupts
- Up to 44 bytes of CMOS RAM
- INTR/MFO pins programmable High/Low and push-pull or open drain

Block Diagram

I_{LKG}	Output High Leakage Current T1, MFO, INTR Pins	$V_{OUT} = V_{CC}$ or GND Outputs Open Drain		± 5.0	μA
I_{CC}	Quiescent Supply Current (Note 7)	$F_{OSC} = 32.768$ kHz $V_{IN} = V_{CC}$ or GND (Note 5) $V_{IN} = V_{CC}$ or GND (Note 6) $V_{IN} = V_{IH}$ or V_{IL} (Note 6)		260 1.0 12.0	μA mA mA
		$F_{OSC} = 4.194304$ MHz or 4.9152 MHz $V_{IN} = V_{CC}$ or GND (Note 6) $V_{IN} = V_{IH}$ or V_{IL} (Note 6)		8 20	mA mA
I_{CC}	Quiescent Supply Current (Single Supply Mode) (Note 7)	$V_{BB} = GND$ $V_{IN} = V_{CC}$ or GND $F_{OSC} = 32.768$ kHz $F_{OSC} = 4.9152$ MHz or 4.194304 MHz		80 7.5	μA mA
I_{BB}	Standby Mode Battery Supply Current (Note 8)	$V_{CC} = GND$ OSC OUT = open circuit, other pins = GND $F_{OSC} = 32.768$ kHz $F_{OSC} = 4.9152$ MHz or 4.194304 MHz		10 400	μA μA
I_{BLK}	Battery, Supply Leakage	$2.2V \leq V_{BB} \leq 4.0V$ other pins at GND $V_{CC} = GND$, $V_{BB} = 4.0V$ $V_{CC} = 5.5V$, $V_{BB} = 2.2V$	-5	1.5	μA μA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: For $F_{OSC} = 4.194304$ or 4.9152 MHz, V_{BB} minimum = 2.8V. In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$. Single Supply Mode: Data retention voltage is 2.2V min. In single Supply Mode (Power connected to V_{CC} pin) $4.5V \leq V_{CC} \leq 5.5V$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: This specification is tested with both the timers and OSC IN driven by a signal generator. Contents of the Test Register = 00(H), the MFO pin is not configured as buffered oscillator out and MFO, INTR, are configured as open drain.

Note 8: This specification is tested with both the timers off, and only OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

AC Electrical Characteristics
 $V_{CC} = 5V \pm 10\%$, $V_{BB} = 3V$, $V_{PFAIL} > V_{IH}$, $C_L = 100$ pF (unless otherwise specified)

Symbol	Parameter	Min	Max	Units
READ TIMING				
t_{AR}	Address Valid Prior to Read Strobe	20		ns
t_{RW}	Read Strobe Width (Note 9)	80		ns
t_{CD}	Chip Select to Data Valid Time		80	ns
t_{RAH}	Address Hold after Read (Note 10)	3		ns
t_{RD}	Read Strobe to Valid Data		70	ns
t_{DZ}	Read or Chip Select to TRI-STATE		60	ns
t_{RCH}	Chip Select Hold after Read Strobe	0		ns
t_{DS}	Minimum Inactive Time between Read or Write Accesses	50		ns
WRITE TIMING				
t_{AW}	Address Valid before Write Strobe	20		ns
t_{WAH}	Address Hold after Write Strobe (Note 10)	3		ns
t_{CW}	Chip Select to End of Write Strobe	90		ns
t_{WW}	Write Strobe Width (Note 11)	80		ns
t_{DW}	Data Valid to End of Write Strobe	50		ns
t_{WDH}	Data Hold after Write Strobe (Note 10)	3		ns
t_{WCH}	Chip Select Hold after Write Strobe	0		ns
INTERRUPT TIMING				
t_{ROLL}	Clock rollover to INTR out is typically 16.5 μ s			

Note 9: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 10: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 11: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output Reference Levels	1.3V
TRI-STATE Reference Levels (Note 13)	Active High +0.5V Active Low –0.5V

Note 12: $C_L = 100$ pF, includes jig and scope capacitance.

Note 13: $S_1 = V_{CC}$ for active low to high impedance measurements.

$S_1 = \text{GND}$ for active high to high impedance measurements.

$S_1 = \text{open}$ for all other timing measurements.

Capacitance ($T_A = 25^\circ\text{C}$, $f = 1$ MHz)

Symbol	Parameter (Note 14)	Typ	Units
C_{IN}	Input Capacitance	5	pF
C_{OUT}	Output Capacitance	7	pF

Note 14: This parameter is not 100% tested.

Note 15: Output rise and fall times 25 ns max (10%–90%) with 100 pF load.

TL/F/9979–2

General Description (Continued)

The DP8571A's interrupt structure provides four basic types of interrupts: Periodic, Alarm/Compare, Timer, and Power Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

One dedicated general purpose interrupt output is provided. A second interrupt output is available on the Multiple Function Output (MFO) pin. Each of these may be selected to generate an interrupt from any source. Additionally, the MFO pin may be programmed to be either as oscillator output or Timer 0's output.

Pin Description

CS, RD, WR (Inputs): These pins interface to μ P control lines. The CS pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the TCP. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} , and the correct crystal select bits in the Real Time Mode Register have been set.

MFO (Output): The multi-function output can be used as a second interrupt output for interrupting the μ P. This pin can also provide an output for the oscillator or the internal Timer 0. The MFO output can be programmed active high or low, open drain or push-pull. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . This pin is configured open drain during battery operation ($V_{BB} > V_{CC}$).

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The INTR output can be programmed active high or low, push-pull or open drain. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . This pin is configured open drain during battery operation ($V_{BB} > V_{CC}$). The output is a DC voltage level. To clear the INTR, write a 1 to the appropriate bit(s) in the Main Status Register.

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μ P's data bus and are used to read from and write to the TCP. When the PFAIL pin goes low and a write is not in progress, these pins are at TRI-STATE.

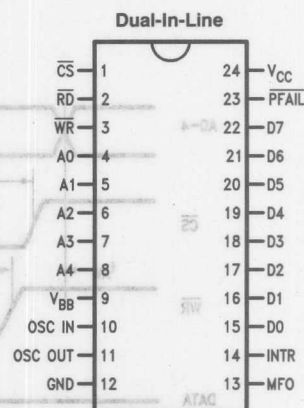

PFAIL (Input): In battery backed mode, this pin can have a digital signal applied to it via some external power detection logic. When PFAIL = logic 0 the TCP goes into a lockout mode, in a minimum of 30 μ s or a maximum of 63 μ s unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

V_{BB} (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be used then this pin must be tied to ground, the TCP programmed for single power supply only, and power applied to the V_{CC} pin.

V_{CC}: This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

TL/F/9979-5

Functional Description

The DP8571A contains a fast access real time clock, two 10 MHz 16-bit timers, interrupt control logic, power fail detect logic, and CMOS RAM. All functions of the TCP are controlled by a set of nine registers. A simplified block diagram that shows the major functional blocks is given in Figure 1.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management
6. Timers

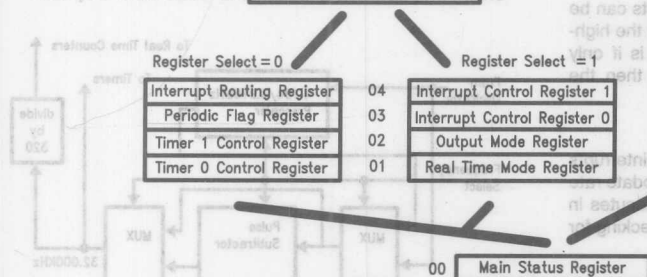

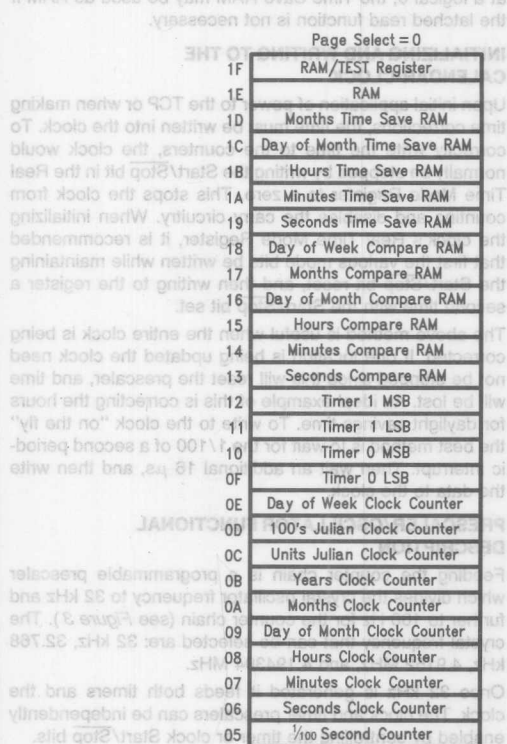

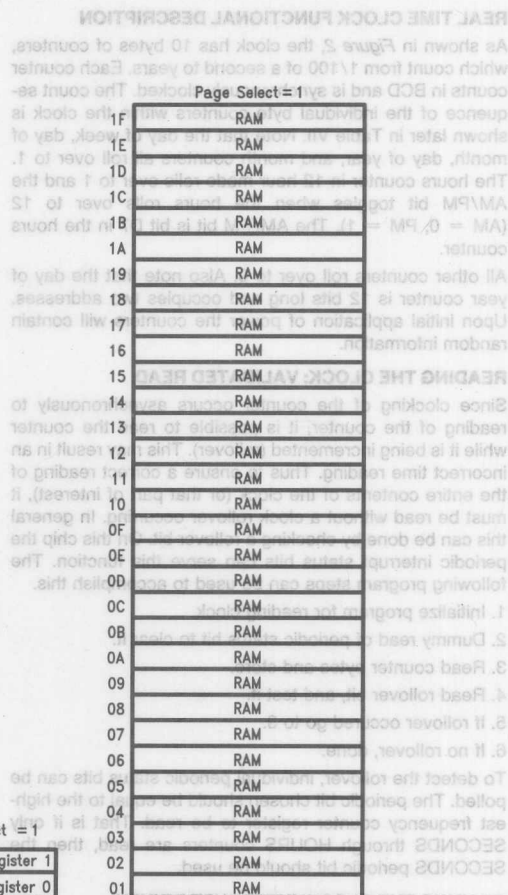

FIGURE 2. DP8571A Internal Memory Map

The memory map of the TCP is shown in the memory addressing table. The memory map consists of two 31 byte pages with a main status register that is common to both pages. A control bit in the Main Status Register is used to select either page. Figure 2 shows the basic concept. Page 0 contains all the clock timer functions, while page 1 has scratch pad RAM. The control registers are split into two separate blocks to allow page 1 to be used entirely as scratch pad RAM. Again a control bit in the Main Status Register is used to select either control register block.

Functional Description (Continued)

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of 1 M Ω . The user should be aware that the control registers will contain random data. The first task to be carried out in an initialization routine is to start the oscillator by writing to the crystal select bits in the Real Time Mode Register. If the DP8571A is configured for single supply mode, an extra 50 μ A may be consumed until the crystal select bits are programmed. The user should also ensure that the TCP is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 10 bytes of counters, which count from 1/100 of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, day of year, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Also note that the day of year counter is 12 bits long and occupies two addresses. Upon initial application of power the counters will contain random information.

READING THE CLOCK: VALIDATED READ

Since clocking of the counter occurs asynchronously to reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time

Save Enable bit (D7) of the Interrupt Routing Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the TCP or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

The above method is useful when the entire clock is being corrected. If one location is being updated the clock need not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the 1/100 of a second periodic interrupt. Then wait an additional 16 μ s, and then write the data to the clock.

PRESCALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3). The crystal frequency that can be selected are: 32 kHz, 32.768 kHz, 4.9152 MHz, and 4.194304 MHz.

Once 32 kHz is generated it feeds both timers and the clock. The clock and timer prescalers can be independently enabled by controlling the timer or clock Start/Stop bits.

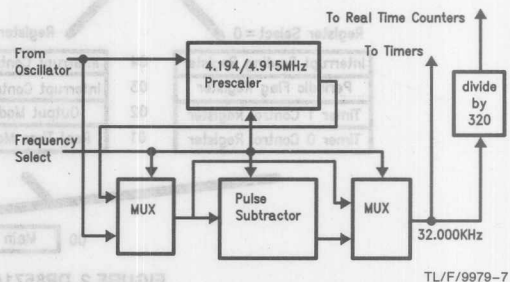

FIGURE 3. Programmable Clock Prescaler Block

Functional Description (Continued)

The oscillator is programmed via the Real Time Mode Register to operate at various frequencies. The crystal oscillator is designed to offer optimum performance at each frequency. Thus, at 32.768 kHz the oscillator is configured as a low frequency and low power oscillator. At the higher frequencies the oscillator inverter is reconfigured. In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the load capacitance specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

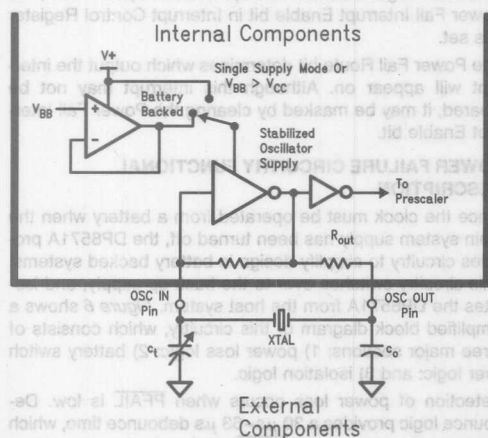

FIGURE 4. Oscillator Circuit Diagram

XTAL	Co	Ct	Rout (Switched Internally)
32/32.768 kHz	47 pF	2 pF–22 pF	150 kΩ to 350 kΩ
4.194304 MHz	68 pF	0 pF–80 pF	500Ω to 900Ω
4.9152 MHz	68 pF	29 pF–49 pF	500Ω to 900Ω

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The TCP has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and also Figure 5 and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1. Any of the interrupts can be routed to either the INTR pin or the MFO pin, depending on how the Interrupt Routing register is programmed. This, for example, enables the user to dedicate the MFO as a non-maskable interrupt pin to the CPU for power failure detection and enable all other interrupts to appear on the INTR pin. The polarity for the active interrupt can be programmed in the Output Mode Register for either active high or low, and open drain or push pull outputs.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Page Select	Address
Main Status Register	X	X	00H
Periodic Flag Register	0	0	03H
Interrupt Routing Register	0	0	04H
Interrupt Control Register 0	1	0	03H
Interrupt Control Register 1	1	0	04H
Output Mode Register	1	0	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all TCP interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the TCP to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system.

Note that the Interrupt Status Flag will only monitor the state of the MFO output if it has been configured as an interrupt output (see Output Mode Register description). This is true, regardless of the state of the Interrupt Routing Register. Thus the Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.

Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1–D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm or Timer interrupts that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the appropriate Alarm or Timer interrupt enable bits are set (see Figure 5). Disabling the periodic bits will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see Figure 5).

To clear a flag in bits D2–D5 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Functional Description (Continued)

Interrupts Fall Into Four Categories:

1. The Timer Interrupts: For description see Timer Section.
2. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
3. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.
4. The Power Fail Interrupt: Issued upon recognition of a power fail condition by the internal sensing logic. The power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The TCP then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 0 3 (BCD), the minutes compare with 1 5 (BCD) and the faster counters with 0 0 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see Figure 5. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register. The Periodic Route bit in the Interrupt Routing Register is used to route the periodic interrupt events to either the INTR output or the MFO output.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μ P clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μ P, but it cannot be cleared; it is cleared automatically by the TCP when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set.

The Power Fail Route bit determines which output the interrupt will appear on. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the DP8571A provides circuitry to simplify design in battery backed systems. This circuitry switches over to the back up supply, and isolates the DP8571A from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when PFAIL is low. De-bounce logic provides a 30 μ s–63 μ s debounce time, which will prevent noise on the PFAIL pin from being interpreted as a system failure. After 30 μ s–63 μ s the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

XTAL	Co	Co	Co
32.768 KHz	47 pf	5 pf–52 pf	150 K Ω to 500 K Ω
4.194304 MHz	58 pf	0 pf–50 pf	500 Ω to 500 Ω
4.194304 MHz	68 pf	59 pf–49 pf	500 Ω to 500 Ω

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION
The TCP has the ability to coordinate processor timing so that it can interface with an interrupt structure that has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and also Figure 5 and Table 1.)

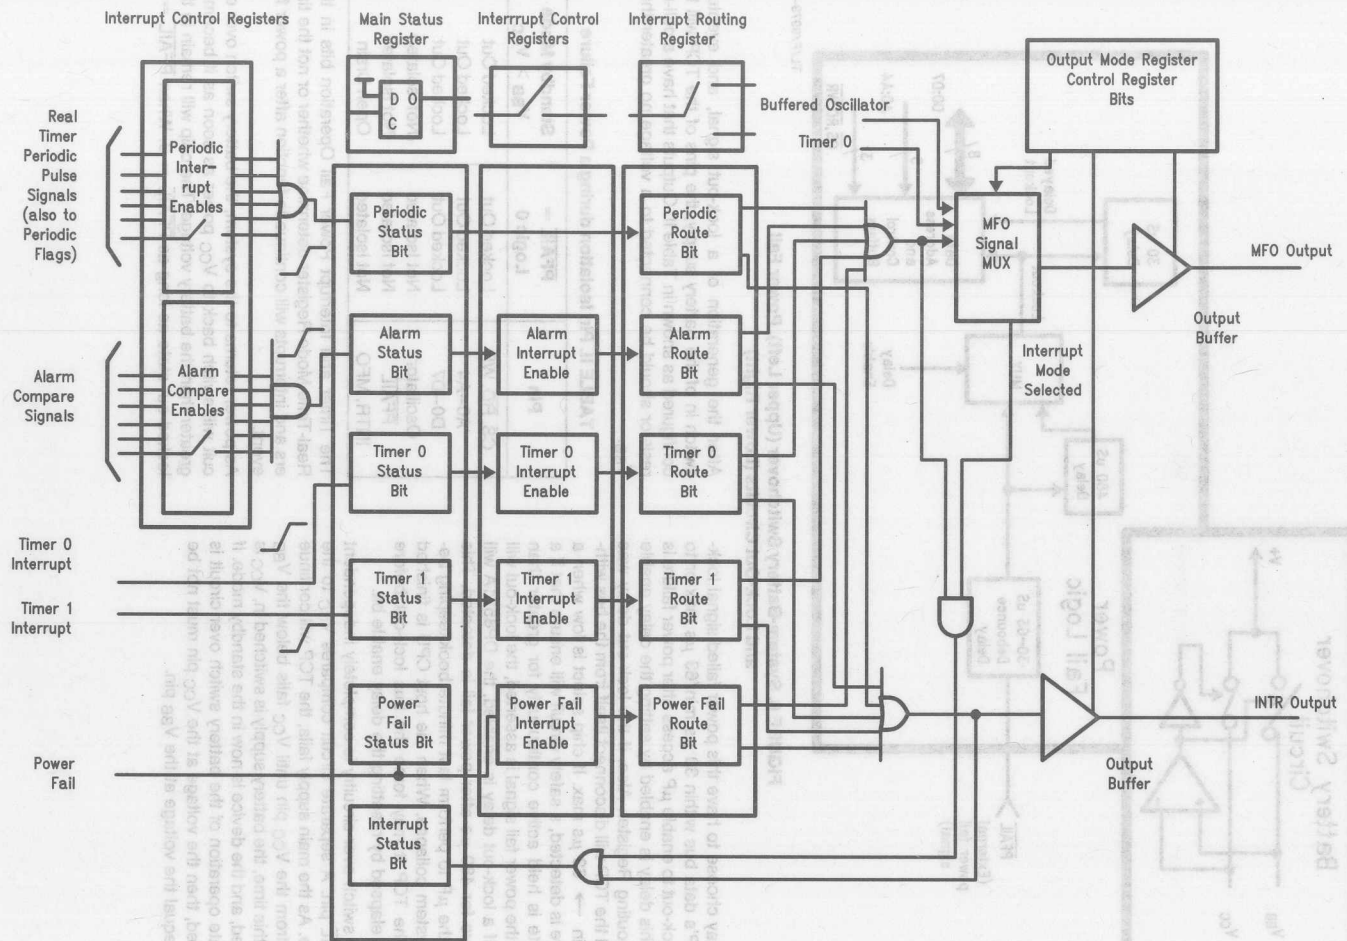

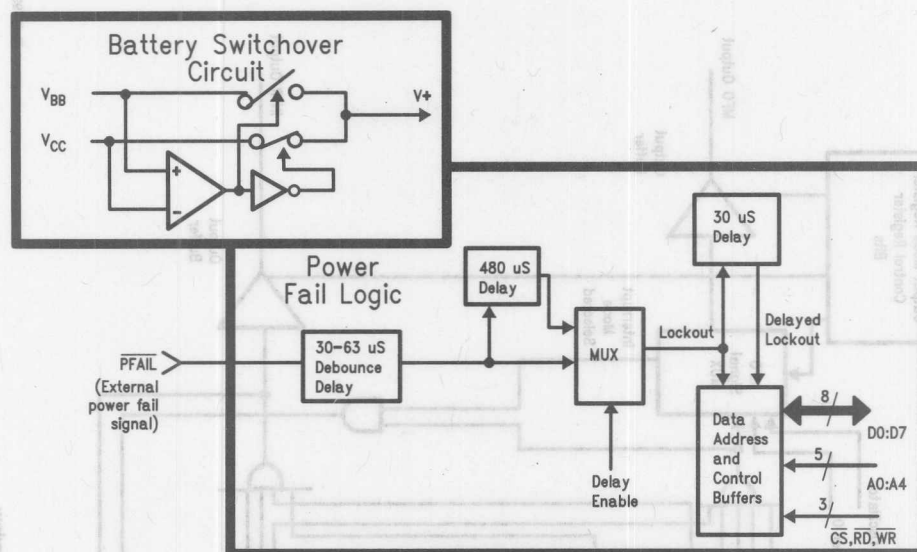

FIGURE 5. Interrupt Control Logic Overview

TL/F/9979-9

Functional Description (Continued)

TL/F/9979-10

FIGURE 6. System-Battery Swchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

The user may choose to have this power failed signal lock-out the TCP's data bus within 30 μ s min/63 μ s max or to delay the lock-out to enable μ P access after power failure is detected. This delay is enabled by setting the delay enable bit in the Routing Register. Also, if the lock-out delay was not enabled the TCP will disconnect itself from the bus within 30 μ s min \rightarrow 63 μ s max. If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than 30 μ s after the power fail signal is asserted, the lock-out will be forced. If a lock-out delay is enabled, the DP8571A will remain active for 480 μ s after power fail is detected. This will enable the μ P to perform last minute bookkeeping before total system collapse. When the host CPU is finished accessing the TCP it may force the bus lock-out before 480 μ s has elapsed by resetting the delay enable bit.

The battery switch over circuitry is completely independent of the PFAIL pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the TCP will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the TCP will be configured as shown in Table II. Outputs that have a pull-up resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	PFAIL = Logic 0	Standby Mode $V_{BB} > V_{CC}$
CS, RD, WR	Locked Out	Locked Out
A0-A4	Locked Out	Locked Out
D0-D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
PFAIL	Not Isolated	Not Isolated
INTR, MFO	Not Isolated	Open Drain

The Timer and Interrupt Power Fail Operation bits in the Real-Time Mode Register determine whether or not the timers and interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as PFAIL = 0. When PFAIL = 1

sure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no external interrupt will be issued. Note that the linear power fail circuitry is switched off automatically when using V_{BB} in standby mode.

LOW BATTERY, INITIAL POWER ON DETECT, AND POWER FAIL TIME SAVE

There are three other functions provided on the DP8571A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, a low battery detect circuit, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

Another status bit is the low battery detect. This bit is set only when the clock is operating under the V_{CC} pin, and when the battery voltage is determined to be less than 2.1V (typical). When the power fail interrupt enable bit is low, it disables the power fail circuit and will also shut off the low battery voltage detection circuit as well.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the PFAL pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The DP8571A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC} and PFAL pins. The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits. Until the crystal select bits are initialized, the DP8571A may consume about 50 μA due to arbitrary oscillator selection at power on.

(This extra 50 μA is not consumed if the battery backed mode is selected).

TIMER FUNCTIONAL DESCRIPTION

The DP8571A contains 2 independent multi-mode timers. Each timer is composed of a 16-bit negative edge triggered

features have been enhanced. The timers can operate in four modes, and in addition, the input clock frequency can be selected from a prescaler over a wide range of frequencies. Furthermore, these timers are capable of generating interrupts and the Timer 0 output signal is available as a hardware output via the MFO pin. Timer 1 output, however, is not available as a hardware output signal. Both the interrupt and MFO outputs are fully programmable active high, or low, open drain, or push-pull.

Figure 7 shows the functional block diagram of one of the timers. The timer consists of a 16-bit counter, two 8-bit input registers, two 8-bit output registers, clock prescaler, mode control logic, and output control logic. The timer and the data registers are organized as two bytes for each timer. Under normal operations a read/write to the timer locations will read or write to the data input register. The timer contents can be read by setting the counter Read bit (RD) in the timer control register.

TIMER INITIALIZATION

The timer's operation is controlled by a set of registers, as listed in Table III. These consist of 2 data input registers and one control register per timer. The data input registers contain the timers count down value. The Timer Control Register is used to set up the mode of operation and the input clock rate. The timer related interrupts can be controlled by programming the Interrupt Routing Register and Interrupt Control Register 0. The timer outputs are configured by the Output Mode Register.

TABLE III. Timer Associated Registers

Register Name	Register Select	Page Select	Address
Timer 0 Data MSB	X	0	10H
Timer 0 Data LSB	X	0	0FH
Timer 0 Control Register	0	0	01H
Timer 1 Data MSB	X	0	12H
Timer 1 Data LSB	X	0	11H
Timer 1 Control Register	0	0	02H
Interrupt Routing Register	0	0	04H
Interrupt Control Reg. 0	1	0	03H
Output Mode Register	1	0	02H

All these registers must be initialized prior to starting the timer(s). The Timer Control Register should first be set to select the timer mode with the timer start/stop bit reset. Then when the timer is to be started the control register should be rewritten identically but with the start/stop bit set.

TIMER OPERATION

Each timer is capable of operation in one of four modes. As mentioned, these modes are programmed in each timer's Control Register which is described later. All four modes operate in a similar manner. They operate on the two 8-bit data words stored into the Data Input Register. At the beginning of a counting cycle the 2 bytes are loaded into the timer and the timer commences counting down towards zero. The exact action taken when zero is reached depends on the mode selected, but in general, the timer output will change state, and an interrupt will be generated if the timer interrupts are unmasked.

Functional Description (Continued)

INPUT CLOCK SELECTION

The input frequency to the timers may be selected. Each timer has a prescaler that gives a wide selection of clocking rates. Table IV shows the range of programmable clocks available and the corresponding setting in the Timer Control Register. Note that the output of Timer 1 may be used as the input to Timer 0. This is a cascade option for the timers and allows them to be clocked as a 32-bit down counter.

TABLE IV. Programmable Timer Input Clocks

C2	C1	C0	Selected Clock
0	0	0	Timer 1 Output
0	0	1	Crystal Oscillator
0	1	0	(Crystal Oscillator)/4
0	1	1	93.5 μ s (10.7 kHz)
1	0	0	1 ms (1 kHz)
1	0	1	10 ms (100 Hz)
1	1	0	1/10 Second (10 Hz)
1	1	1	1 Second (1 Hz)

Note that the second and third selections are not fixed frequencies, but depend on the crystal oscillator frequency chosen.

Since the input clock frequencies are usually running asynchronously to the timer Start/Stop control bit, a 1 clock cycle error may result. This error results when the Start/Stop occurs just after the clock edge (max error). To minimize this error on all clocks an independent prescaler is used for each timer and is designed so that its Start/Stop error is less than 1 clock cycle.

The count hold/gate bit in the Timer Control Register can be used to suspend the timer operation in modes 0, 1, and 2 (in mode 3 it is the trigger input). Suspending the tim-

er causes the same synchronization error that starting the timer does. The range of errors is specified in Table V.

TABLE V. Maximum Synchronization Errors

Clock Selected	Error
External	+ Ext. Clock Period
Crystal	+ 1 Crystal Clock Period
Crystal/4	+ 1 Crystal Clock Period
10.7 kHz	+ 32 μ s
1 kHz	+ 32 μ s
100 Hz	+ 32 μ s
10 Hz	+ 32 μ s
1 Hz	+ 32 μ s

MODES OF OPERATION

Bits M0 and M1 in the Timer Control Registers are used to specify the modes of operation. The mode selection is described in Table VI.

TABLE VI. Programmable Timer Modes of Operation

M1	M0	Function	Modes
0	0	Single Pulse Generator	Mode 0
0	1	Rate Generator, Pulse Output	Mode 1
1	0	Square Wave Output	Mode 2
1	1	Retriggerable One Shot	Mode 3

MODE 0: SINGLE PULSE GENERATOR

When the timer is in this mode the output will be initially low if the Timer Start/Stop bit is low (stopped). When this mode is initiated the timer output will go high on the next falling edge of the prescaler's input clock, the contents of the

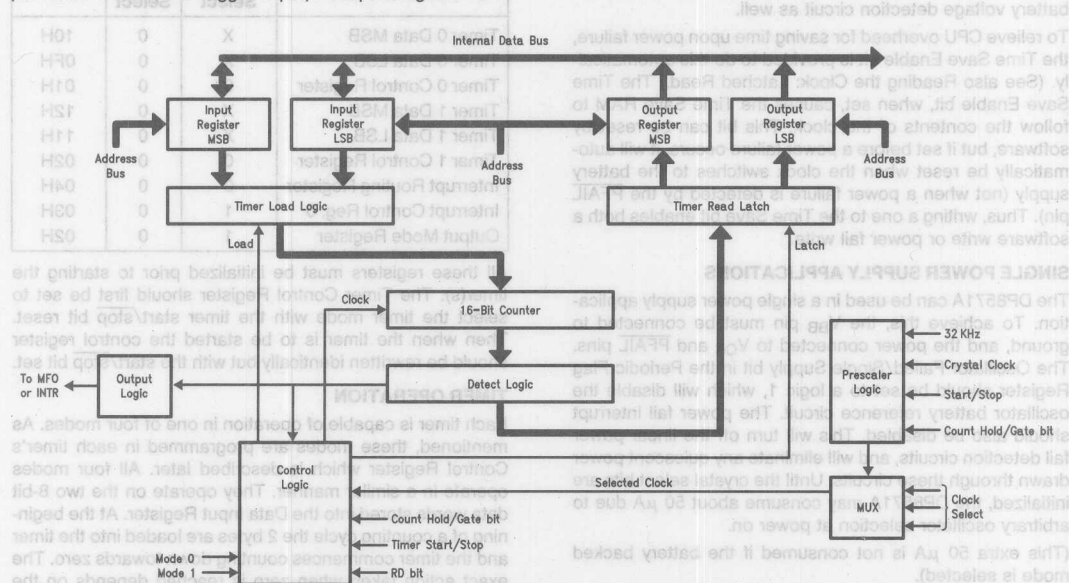

FIGURE 7. DP8571A Timer Block Diagram

Functional Description (Continued)

input data registers are loaded into the timer. The output will stay high until the counter reaches zero. At zero the output is reset. The result is an output pulse whose duration is equal to the input clock period times the count value (N) loaded into the input data register. This is shown in *Figure 8*.

$$\text{Pulse Width} = \text{Clock Period} \times N$$

An interrupt is generated when the zero count is reached. This can be used for one-time interrupts that are set to occur a certain amount of time in the future. In this mode the Timer Start/Stop bit (TSS) is automatically reset upon zero detection. This removes the need to reset TSS before starting another operation.

The count down operation may be temporarily suspended either under software control by setting the Count Hold/Gate bit in the timer register high, or in hardware by setting the G0 or G1 pin high.

The above discussion assumes that the MFO output is programmed to be non-inverting outputs (active high). If the polarity of the output waveform is wrong for the application the polarity can be reversed by configuring the Output Mode Register. The drive configuration can also be programmed to be push pull or open drain.

MODE 1: RATE GENERATOR

When operating in this mode the timer will operate continuously. Before the timer is started its output is low. When the timer is started the input data register contents are loaded into the counter on the negative clock edge and the output is set high (again assuming the Output Mode Register is programmed active high). The timer will then count down to zero. Once the zero count is reached the output goes low

for one clock period of the timer clock. Then on the next clock the counter is reloaded automatically and the count-down repeats itself. The output, shown in *Figure 9*, is a waveform whose pulse width and period is determined by N, the input register value, and the input clock period:

$$\text{Period} = (N + 1) (\text{Clock Period})$$

$$\text{Pulse Width} = \text{Clock Period}$$

Again, the output polarity is controllable as in mode 0. If enabled, an interrupt is generated whenever the zero count is reached. This can be used to generate a periodic interrupt.

MODE 2: SQUARE WAVE GENERATOR

This mode is also cyclic but in this case a square wave rather than a pulse is generated. The output square wave period is determined by the value loaded into the timer input register. This period and the duty cycle are:

$$\text{Period} = 2(N + 1) (\text{Clock Period}) \quad \text{Duty Cycle} = 0.5$$

When the timer is stopped the output will be low, and when the Start/Stop bit is set high the timer's counter will be loaded on the next clock falling transition and the output will be set high.

The output will be toggled after the zero count is detected and the counter will then be reloaded, and the cycle will continue. Thus, every $N + 1$ counts the output gets toggled, as shown in *Figure 10*. Like the other modes the timer operation can be suspended by setting the count hold/gate bit (CHG) in the Timer Control Register. An interrupt will be generated every falling edge of the timer output, if enabled.

FIGURE 8. Typical Waveforms for Timer Mode 0 (MFO Output Programmed Active High)

FIGURE 9. Timing Waveforms for Timer Mode 1 (MFO Output Programmed Active High)

Functional Description (Continued)

FIGURE 10. Timing Waveforms for Timer Mode 2
(MFO Output Programmed Active High)

MODE 3: RETRIGGERABLE ONE SHOT

Once the timer Start/Stop bit is set the output stays inactive, and nothing happens until the Count Hold/Gate (CHG) bit is set in the timer control register. When a transition occurs the one shot output is set active immediately; the counter is loaded with the value in the input register on the next transition of the input clock and the countdown begins. If a retrigger occurs, regardless of the current counter value, the counters will be reloaded with the value in the input register and the counter will be restarted without changing the output state. See Figure 11. A trigger count can occur at any time during the count cycle. In this mode the timer will output a single pulse whose width is determined by the value in the input data register (N) and the input clock period.

$$\text{Pulse Width} = \text{Clock Period} \times N$$

The timer will generate an interrupt only when it reaches a count of zero. This timer mode is useful for continuous "watch dog" timing, line frequency power failure detection, etc.

READING THE TIMERS

National has discovered that some users may encounter unacceptable error rates for their applications when reading the timers on the fly asynchronously. When doing asynchronous reads of the timers, an error may occur. The error is that a successive read may be larger than the previous read. Experimental results indicate that the typical error rate is approximately one per 29,000 under the following conditions:

Timer clock frequency of 5 MHz.

Computer: 386/33 MHz PC/AT

Program: Microsoft "C" 6.0, reading and saving timer contents in a continuous loop.

FIGURE 11. Timing Waveforms for Timer Mode 3, MFO Output Programmed Active High

Those users who find the error rate unacceptable may reduce the problem effectively to zero by employing a hardware work-around that synchronizes the writing of the read bit to the timer control register with respect to the decrementing clock. Refer to Figure 1 in Appendix A, for a suggested hardware work-around.

A software work-around can reduce the errors but not as substantial as a hardware work-around. Software work-arounds are based on observations that the read following a bad read appeared to be valid.

This problem concerns statistical probability and is similar to metastability issues. For more information on metastability, refer to 1991 IEEE transactions on Custom Integrated Circuits Conference, paper by T.J. Gabara of AT&T Bell Laboratories, page 29.4.1.

Normally reading the timer data register addresses, 0FH and 10H for Timer 0 and 11H and 12H for Timer 1 will result in reading the input data register which contains the preset value for the timers.

To read the contents of a timer, the μP first sets the timer read bit in the appropriate Timer Control Register high. This will cause the counter's contents to be latched to 2-bit-8-bit output registers, and will enable these registers to be read if the μP reads the timer's input data register addresses. On reading the LSB byte the timer read bit is internally reset and subsequent reads of the timer locations will return the input register values.

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 32 locations at one time. An internal switching scheme provides a total of 67 locations.

This complete address space is organized into two pages. Page 0 contains two blocks of control registers, timers, real time clock counters, and special purpose RAM, while page 1 contains general purpose RAM. Using two blocks enables the 9 control registers to be mapped into 5 locations. The only register that does not get switched is the Main Status Register. It contains the page select bit and the register select bit as well as status information.

Functional Description (Continued)

A memory map is shown in Figure 2 and register addressing in Table VII. They show the name, address and page locations for the DP8571A.

TABLE VII. Register/Counter/RAM Addressing for DP8571A

Note 1: PS—Page Select (Bit D7 of Main Status Register)

Note 2: RS—Register Select (Bit D6 of Main Status Register)

Note 3: The LSB counters count 0-99 until the hundreds of days counter reaches 3. Then the LSB counters count to 65 or 66 (if a leap year). The rollover is from 365/366 to 1.

MAIN STATUS REGISTER

TL/F/9979-16

The Main Status Register is always located at address 0 regardless of the register block or the page selected.

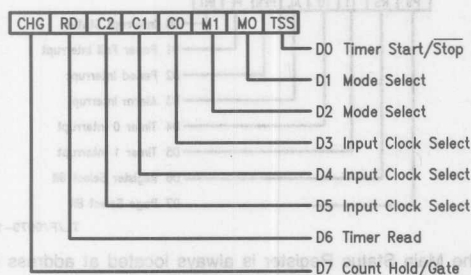

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3-D5 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1-D5: These five bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μP will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PF_{FAIL} pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1, D3-D5 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D6 and D7: These bits are Read/Write bits that control which register block or RAM page is to be selected. Bit D6 controls the register block to be accessed (see memory map). The memory map of the clock is further divided into two memory pages. One page is the registers, clock and timers, and the second page contains 31 bytes of general purpose RAM. The page selection is determined by bit D7.

Functional Description (Continued)

TIMER 0 AND 1 CONTROL REGISTER

TL/F/9979-17

These registers control the operation of the timers. Each timer has its own register.

D0: This bit will Start (1) or Stop (0) the timer. When the timer is stopped the timer's prescaler and counter are reset, and the timer will restart from the beginning when started again. In mode 0 on time out the TSS bit is internally reset.

D1 and D2: These control the count mode of the timers. See Table VI.

D3–D5: These bits control which clock signal is applied to the timer's counter input. Refer to Table IV for details.

D6: This is the read bit. If a one is written into this location it will cause the contents of the timer to be latched into a holding register, which can be read by the μP at any time. Reading the least significant byte of the timer will reset the RD bit. The timer read cycle can be aborted by writing RD to zero.

D7: The CHG bit has two mode dependent functions. In modes 0 through 2 writing a one to this bit will suspend the timer operation (without resetting the timer prescaler). However, in mode 3 this bit is used to trigger or re-trigger the count sequence as with the gate pins. If retriggering is desired using the CHG bit, it is not necessary to write a zero to this location prior to the re-trigger. The action of further writing a one to this bit will re-trigger the count.

PERIODIC FLAG REGISTER

TL/F/9979-18

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0–D5 are read only bits, D6 and D7 are read/write.

D0–D5: These bits are set by the real time rollover events: (Time Change = 1). The bits are reset when the register is read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure may be caused are: failure of the crystal, shorting OSC IN or OSC OUT to GND or V_{CC} , removal of crystal, removal of battery when in the battery backed mode (when a "0" is written to D6), lowering the voltage at the V_{BB} pin to a value less than 2.2V when in the battery backed mode. Bit D6 is automatically set to 1 on initial power-up or an oscillator fail event. The oscillator fail flag is reset by writing a one to the clock start/stop bit in the Real Time Mode Register, with the crystal oscillating.

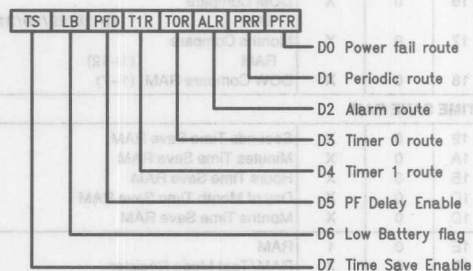

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the DP8571A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to $V_{CC}-0.4V$.

For single supply mode operation, the V_{BB} pin should be connected to GND and the PFAIL pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table VII). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

INTERRUPT ROUTING REGISTER

TL/F/9979-19

D0–D4: The lower 5 bits of this register are associated with the main interrupt sources created by this chip. The purpose of this register is to route the interrupts to either the MFO (multi-function pin), or to the main interrupt pin. When any bit is set the associated interrupt signal will be sent to the MFO pin, and when zero it will be sent to the INTR pin.

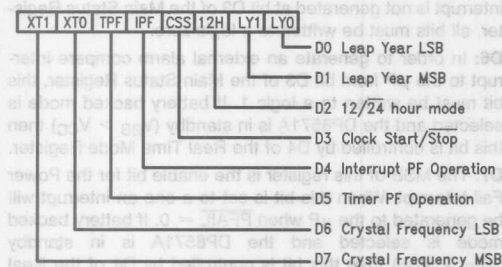

power fail interrupt. After a power failure is detected but prior to the 480 μ s delay timing out, the host μ P may force immediate lock out by resetting the Delay Enable bit. Note if this bit is a 0 when power fails then after a delay of 30 μ s min/63 μ s max the μ P cannot read the chip.

D6: This read only bit is set and reset by the voltage at the V_{BB} pin. It can be used by the μ P to determine whether the battery voltage at the V_{BB} pin is getting too low. A comparator monitors the battery and when the voltage is lower than 2.1V (typical) this bit is set. The power fail interrupt must be enabled to check for a low battery voltage.

D7: Time Save Enable bit controls the loading of real-time-clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

TL/F/9979-20

D0-D1: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped and the prescaler is cleared. When the TCP is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Timer interrupts will also be functional provided that bit D5 is also set. Note that the MFO and INTR pins are configured as open drain in standby mode.

If bit D4 is set to a zero then interrupt control register 0 and bits D6 and D7 of interrupt control register 1 will be reset when the TCP enters the standby mode ($V_{BB} > V_{CC}$). They will have to be re-configured when system (V_{CC}) power is restored.

D5: This bit controls the operation of the timers in standby mode. If set to a one the timers will continue to function when the TCP is in standby mode. The input pins TCK, G0, G1 are locked out in standby mode, and cannot be used.

Therefore external control of the timers is not possible in standby mode. Note also that MFO and T1 pins are automatically reconfigured open drain during standby.

D6 and D7: These two bits select the crystal clock frequency as per the following table:

XT1	XT0	Crystal Frequency
0	0	32.768 kHz
0	1	4.194304 MHz
1	0	4.9152 MHz
1	1	32.000 kHz

All bits are Read/Write, and any mode written into this register can be determined by reading the register. On initial power up these bits are random.

OUTPUT MODE REGISTER

TL/F/9979-21

Functional Description (Continued)

D0 and D1: These bits are available as general purpose RAM.

D2: This bit, when set to a one makes the INTR output pin active high, and when set to a zero, it makes this pin active low.

D3: This bit controls whether the INTR pin is an open drain or push-pull output. A one indicates push-pull.

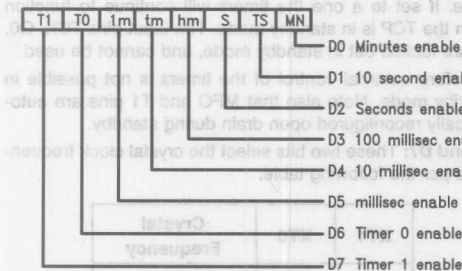

D4: This bit, when set to a one makes the MFO output pin active high, and when set to a zero, it makes this pin active low.

D5: This bit controls whether the MFO pin is an open drain or push-pull output. A one indicates push-pull.

D6 and D7: These bits are used to program the signal appearing at the MFO output, as follows:

D7	D6	MFO Output Signal
0	0	2nd Interrupt
0	1	Timer 0 Waveform
1	X	Buffered Crystal Oscillator

INTERRUPT CONTROL REGISTER 1

TL/F/9979-22

If battery backed mode is selected and the DP8571A is in standby ($V_{BB} > V_{CC}$) then all bits are controlled by D4 of the Real Time Mode Register.

D0–D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the periodic time chosen, but after the first interrupt all subse-

quent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin.

D6 and D7: These are individual timer enable bits. A one written to these bits enable the timers to generate interrupts to the μP .

INTERRUPT CONTROL REGISTER 1

TL/F/9979-23

D0–D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the "always equal" state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If battery backed mode is selected and the DP8571A is in standby ($V_{BB} > V_{CC}$) then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when $PFAIL = 0$. If battery backed mode is selected and the DP8571A is in standby ($V_{BB} > V_{CC}$) then this bit is controlled by D4 of the Real Time Mode Register.

This bit also enables the low battery detection analog circuitry.

If the user wishes to mask the power fail interrupt, but utilize the analog circuitry, this bit should be enabled, and the Routing Register can be used to route the interrupt to the MFO pin. The MFO pin can then be left open or configured as the Timer 0 or buffered oscillator output.

Leap Year Counter	LYB	LY1
Leap Year Current Year	0	0
Leap Year Last Year	1	0

Application Hints

Suggested initialization procedure for DP8571A in battery backed applications that use the V_{BB} pin.

1. Enter the test mode by writing a 1 to bit D7 in the Periodic Flag Register.
2. Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
3. Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1, 2, 3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.
4. After power on (V_{CC} and V_{BB} powered), select the correct crystal frequency bits (D7, D6 in the Real Time Mode Register) as shown in Table 1.

Table 1

Frequency	D7	D6
32.768 KHz	0	0
4.194304 MHz	0	1
4.9152 MHz	1	0
32.0 KHz	1	1

5. Enter a software loop that does the following:
Set a 3 second(approx) software counter. The crystal oscillator may take 1 second to start.
- 5.1 Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Make sure the crystal select bits remain the same as in step 1. Under normal operation, this bit can be set only if the oscillator is running. During the software loop, RAM, real time counters, output configu-

ration, interrupt control and timer functions may be initialized.

6. Test bit D6 in the Periodic Flag Register:
IF a 1, go to 5.1 If this bit remains a 1 after 3 seconds, then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 M Ω .
IF a 0, then the oscillator is running, go to step 7.
7. Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the OSC fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder, bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation.
The only method to ensure the chip is in the battery backed mode is to measure the waveform at the OSC OUT pin. If the battery backed mode was selected successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC} . The measurement should be made with a high impedance low capacitance probe (10 M Ω , 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.
8. Write a 1 to bit D7 of Interrupt Control Register 1. This action enables the PFAIL pin and associated circuitry.
9. Write a 1 to bit D4 of the Real Time Mode Register. This action ensures that bit D7 of Interrupt Control Register 1 remains a 1 when $V_{BB} > V_{CC}$ (standby mode).
10. Initialize the rest of the chip as needed.

Typical Application

*These components may be necessary to meet UL requirements for lithium batteries. Consult battery manufacturer.

DP8572A/DP8572AM Real Time Clock (RTC)

General Description

The DP8572A (8572AM—militarized version) is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports. The address space is organized as 2 software selectable pages of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, and the Time Save RAM. Any of the RAM locations that are not being used for their intended purpose may be used as general purpose CMOS RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week, day of month and day of year counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the crystal and two capacitors. The choice of crystal frequency is program selectable.

Power failure logic and control functions have been integrated on chip. This logic is used by the RTC to issue a power fail interrupt, and lock out the μ p interface. The time power fails may be logged into RAM automatically when $V_{BB} >$

V_{CC} . Additionally, two supply pins are provided. When $V_{BB} > V_{CC}$, internal circuitry will automatically switch from the main supply to the battery supply. Status bits are provided to indicate initial application of battery power, system power, and low battery detect. (Continued)

Features

- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week and day of years counters
 - Four selectable oscillator frequencies
 - Parallel resonant oscillator
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, and power fail interrupts
- Up to 44 bytes of CMOS RAM
- MIL-STD-883C compliant
- SMD #5962-91641-01MJX (future)

I_{BB}	Standby Mode Battery Supply Current (Note 7)	$V_{CC} = GND$ OSC OUT = open circuit, other pins = GND $F_{OSC} = 32.768$ kHz $F_{OSC} = 4.9152$ MHz or 4.194304 MHz		10 400	μA μA
I_{BLK}	Battery Leakage	$2.2V \leq V_{BB} \leq 4.0V$ other pins at GND $V_{CC} = GND$, $V_{BB} = 4.0V$ $V_{CC} = 5.5V$, $V_{BB} = 2.2V$	-5	1.5	μA μA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: For $F_{OSC} = 4.194304$ or 4.9152 MHz, V_{BB} minimum = 2.8V. In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$.
Single Supply Mode: Data retention voltage is 2.2V min.

In single Supply Mode (Power connected to V_{CC} pin) $4.5V \leq V_{CC} \leq 5.5V$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

8572A

AC Electrical Characteristics

 $V_{CC} = 5V \pm 10\%$, $V_{BB} = 3V$, $V_{PFAIL} > V_{IH}$, $C_L = 100$ pF (unless otherwise specified)

Symbol	Parameter	Min	Max	Units
READ TIMING				
t_{AR}	Address Valid Prior to Read Strobe	20		ns
t_{RW}	Read Strobe Width (Note 8)	80		ns
t_{CD}	Chip Select to Data Valid Time		80	ns
t_{RAH}	Address Hold after Read (Note 9)	3		ns
t_{RD}	Read Strobe to Valid Data		70	ns
t_{DZ}	Read or Chip Select to TRI-STATE		60	ns
t_{RCH}	Chip Select Hold after Read Strobe	0		ns
t_{DS}	Minimum Inactive Time between Read or Write Accesses	50		ns
WRITE TIMING				
t_{AW}	Address Valid before Write Strobe	20		ns
t_{WAH}	Address Hold after Write Strobe (Note 9)	3		ns
t_{CW}	Chip Select to End of Write Strobe	90		ns
t_{WW}	Write Strobe Width (Note 10)	80		ns
t_{DW}	Data Valid to End of Write Strobe	50		ns
t_{WDH}	Data Hold after Write Strobe (Note 9)	3		ns
t_{WCH}	Chip Select Hold after Write Strobe	0		ns
INTERRUPT TIMING				
t_{ROLL}	Clock Rollover to \overline{INTR} Out is Typically 16.5 μ s			

Note 8: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 9: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 10: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output Reference Levels	1.3V
TRI-STATE Reference Levels (Note 12)	Active High +0.5V Active Low –0.5V

General Description (Continued)

The DP8572A's interrupt structure provides three basic types of interrupts: Periodic, Alarm/Compare, and Power Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

Pin Description

CS, RD, WR (Inputs): These pins interface to μP control lines. The CS pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the RTC. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} , and the correct crystal select bits in the Real Time Mode Register have been set.

MFO (Output): The multi-function output can be used as a second interrupt output for interrupting the μP . This pin can also provide an output for the oscillator. The MFO output is configured as push-pull, active high for normal or single power supply operation and as an open drain during standby mode ($V_{BB} > V_{CC}$). If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} .

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The INTR output is permanently configured active low, open drain. If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . The output is a DC voltage level. To clear the INTR, write a 1 to the appropriate bit(s) in the Main Status Register.

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μP 's data bus and are used to read from and write to the RTC. When the PFAIL pin goes low and a write is not in progress, these pins are at TRI-STATE.

PFail (Input): In battery backed mode, this pin can have a digital signal applied to it via some external power detection logic. When PFAIL = logic 0 the RTC goes into a lockout mode, in a minimum of 30 μs or a maximum of 63 μs unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

VBB (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be used then this pin must be tied to ground, the RTC programmed for single power supply only, and power applied to the V_{CC} pin.

VCC: This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

registers. A simplified block diagram that shows the major functional blocks is given in *Figure 1*.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management

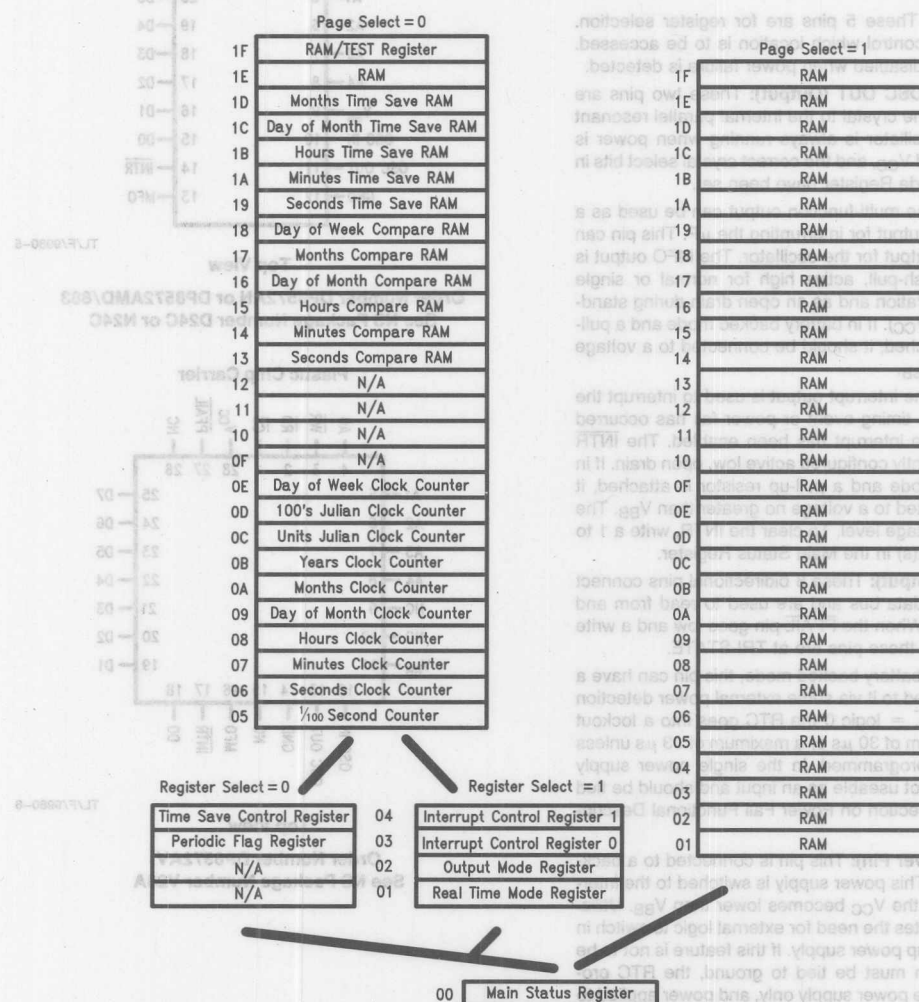

FIGURE 2. DP8572A Internal Memory Map

TL/F/9880-7

Functional Description (Continued)

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of $1\text{ M}\Omega$. The user should be aware that the control registers will contain random data. The first task to be carried out in an initialization routine is to start the oscillator by writing to the crystal select bits in the Real Time Mode Register. If the DP8572A is configured for single supply mode, an extra $50\text{ }\mu\text{A}$ may be consumed until the crystal select bits are programmed. The user should also ensure that the RTC is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 10 bytes of counters, which count from $1/100$ of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, day of year, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Also note that the day of year counter is 12 bits long and occupies two addresses. Upon initial application of power the counters will contain random information.

READING THE CLOCK: VALIDATED READ

Since clocking of the counter occurs asynchronously to reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate, and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time

Save Enable bit (D7) of the Time Save Control Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the RTC or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

The above method is useful when the entire clock is being corrected. If one location is being updated the clock need not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the $1/100$ of a second periodic interrupt. Then wait an additional $16\text{ }\mu\text{s}$, and then write the data to the clock.

PRESCALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3). The crystal frequency that can be selected are: 32 kHz, 32.768 kHz, 4.9152 MHz, and 4.194304 MHz.

FIGURE 3. Programmable Clock Prescaler Block

TL/F/9980-8

Functional Description (Continued)

The oscillator is programmed via the Real Time Mode Register to operate at various frequencies. The crystal oscillator is designed to offer optimum performance at each frequency. Thus, at 32.768 kHz the oscillator is configured as a low frequency and low power oscillator. At the higher frequencies the oscillator inverter is reconfigured. In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the **load capacitance** specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

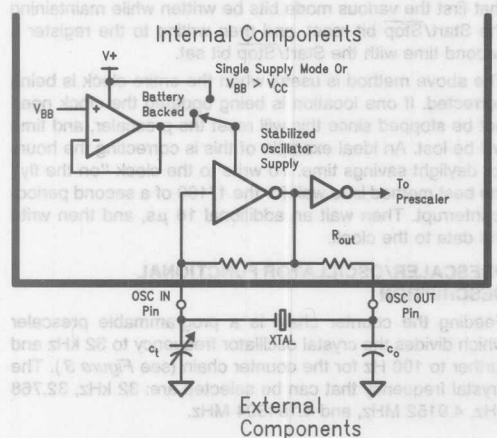

FIGURE 4. Oscillator Circuit Diagram

XTAL	C _o	C _t	R _{out} (Switched Internally)
32/32.768 kHz	47 pF	2 pF–22 pF	150 kΩ to 350 kΩ
4.194304 MHz	68 pF	0 pF–80 pF	500Ω to 900Ω
4.9152 MHz	68 pF	29 pF–49 pF	500Ω to 900Ω

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The RTC has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and also Figure 5 and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Page Select	Address
Main Status Register	X	X	00H
Periodic Flag Register	0	0	03H
Interrupt Control Register 0	1	0	03H
Interrupt Control Register 1	1	0	04H
Output Mode Register	1	0	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all RTC interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the RTC to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system. (The Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.) Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1–D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm comparisons that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the Alarm interrupt enable bit is set (see Figure 5).

Disabling the periodic interrupts will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see Figure 5).

To clear a flag in bits D2 and D3 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Functional Description (Continued)

Interrupts Fall Into Three Categories:

1. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
2. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.
3. The Power Fail Interrupt: Issued upon recognition of a power fail condition by the internal sensing logic. The power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The RTC then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 03 (BCD), the minutes compare with 15 (BCD) and the faster counters with 00 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see

Figure 5. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μP clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μP , but it cannot be cleared; it is cleared automatically by the RTC when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the DP8572A provides circuitry to simplify design in battery backed systems. This switches over to the back up supply, and isolates itself from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when PFAIL is low. De-bounce logic provides a 30 μs –63 μs debounce time, which will prevent noise on the PFAIL pin from being interpreted as a system failure. After 30 μs –63 μs the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

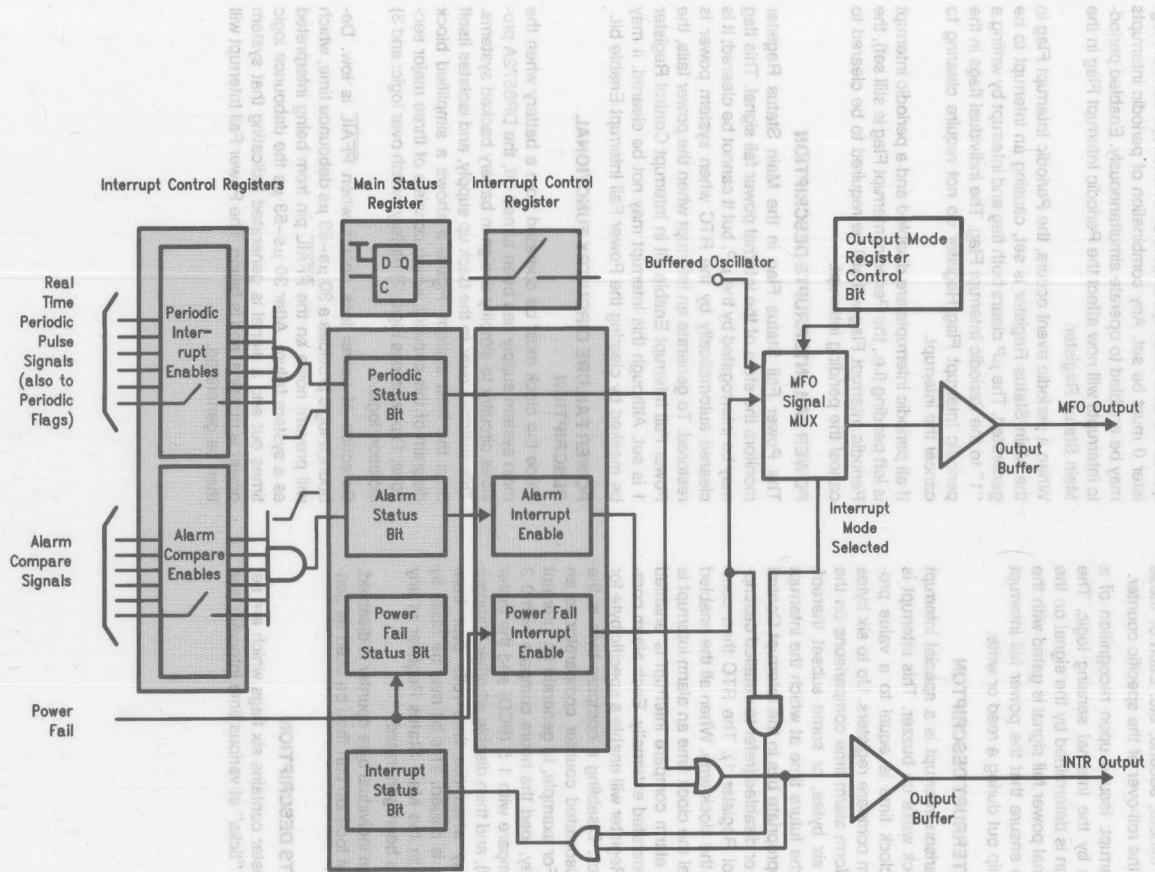

FIGURE 5. Interrupt Control Logic Overview

TL/F/9986

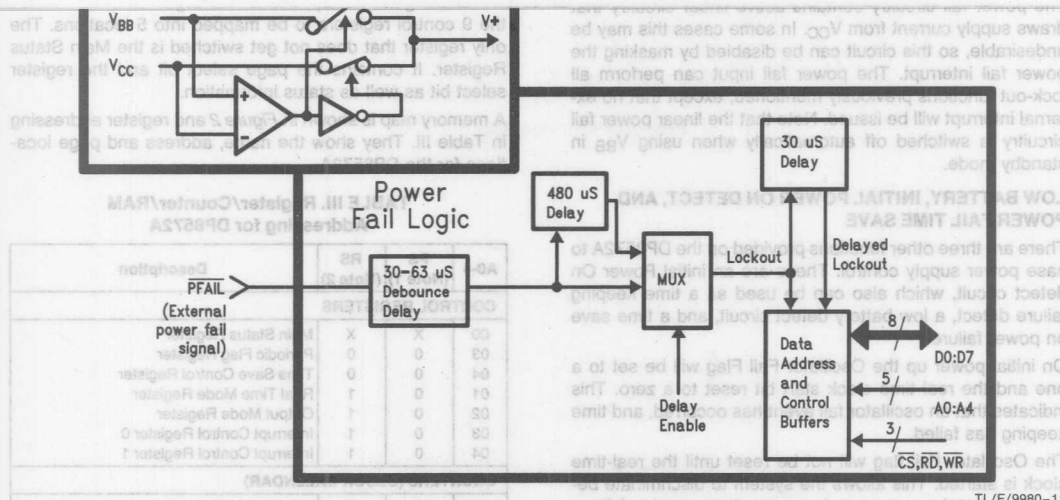

FIGURE 6. System-Battery Switchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than 30 μ s after the power fail signal is asserted, the lock-out will be forced. If a lock-out delay is enabled, the DP8572A will remain active for 480 μ s after power fail is detected. This will enable the μ P to perform last minute bookkeeping before total system collapse. When the host CPU is finished accessing the RTC it may force the bus lock-out before 480 μ s has elapsed by resetting the delay enable bit.

The battery switch over circuitry is completely independent of the PFAIL pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the RTC will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the RTC will be configured as shown in Table II. Outputs that have a pull-up

resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	PFAIL = Logic 0	Standby Mode $V_{BB} > V_{CC}$
CS, RD, WR	Locked Out	Locked Out
A0-A4	Locked Out	Locked Out
D0-D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
PFAIL	Not Isolated	Not Isolated
INTR, MFO	Not Isolated	Open Drain

The Interrupt Power Fail Operation bit in the Real-Time Mode Register determine whether or not the interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as PFAIL = 0. When PFAIL = 1, the chip will exit the locked out state. The power fail interrupt should also be disabled. This will turn off the linear power tail detection circuit, and will eliminate any quiescent power drawn through these circuits. Until the crystal select bits are initialized, the DP8572A may consume about 50 μ A due to arbitrary oscillator selection at power on.

(This extra 50 μ A is not consumed if the battery backed mode is selected).

DETAILED REGISTER DESCRIPTION
There are 3 external address bits. Thus, the host microprocessor has access to 28 locations at one time. An internal switching scheme provides a total of 64 locations.

Functional Description (Continued)

the chip is unlocked, but only after another 30 μ s min \rightarrow 63 μ s max debounce time. The system designer must ensure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no external interrupt will be issued. Note that the linear power fail circuitry is switched off automatically when using V_{BB} in standby mode.

LOW BATTERY, INITIAL POWER ON DETECT, AND POWER FAIL TIME SAVE

There are three other functions provided on the DP8572A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, a low battery detect circuit, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

Another status bit is the low battery detect. This bit is set only when the clock is operating under the V_{CC} pin, and when the battery voltage is determined to be less than 2.1V (typical). When the power fail interrupt enable bit is low, it disables the power fail circuit and will also shut off the low battery voltage detection circuit as well.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the PFAIL pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The DP8572A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC} and PFAIL pins. The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits. Until the crystal select bits are initialized, the DP8572A may consume about 50 μ A due to arbitrary oscillator selection at power on.

(This extra 50 μ A is not consumed if the battery backed mode is selected).

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 28 locations at one time. An internal switching scheme provides a total of 61 locations.

This complete address space is organized into two pages. Page 0 contains two blocks of control registers, timers, real time clock counters, and special purpose RAM, while page 1 contains general purpose RAM. Using two blocks enables the 9 control registers to be mapped into 5 locations. The only register that does not get switched is the Main Status Register. It contains the page select bit and the register select bit as well as status information.

A memory map is shown in Figure 2 and register addressing in Table III. They show the name, address and page locations for the DP8572A.

TABLE III. Register/Counter/RAM Addressing for DP8572A

Note 1: PS—Page Select (Bit D7 of Main Status Register)

Note 2: RS—Register Select (Bit D6 of Main Status Register)

Note 3: The LSB counters count 0 \rightarrow 99 until the hundreds of days counter reaches 3. Then the LSB counters count to 65 or 66 (if a leap year). The rollover is from 365/366 to 1.

Functional Description (Continued)

MAIN STATUS REGISTER

TL/F/9980-12

The Main Status Register is always located at address 0 regardless of the register block or the page selected.

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1–D3: These three bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μP will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PFAIL pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1 and D3 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D4–D5: General purpose RAM bits.

D6 and D7: These bits are Read/Write bits that control which register block or RAM page is to be selected. Bit D6 controls the register block to be accessed (see memory map). The memory map of the clock is further divided into two memory pages. One page is the registers, clock and timers, and the second page contains 31 bytes of general purpose RAM. The page selection is determined by bit D7.

PERIODIC FLAG REGISTER

TL/F/9980-13

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0–D5 are read only bits, D6 and D7 are read/write.

D0–D5: These bits are set by the real time rollover events: (Time Change = 1). The bits are reset when the register is read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure might be caused are: failure of the crystal, shorting OSC.IN or OSC.OUT to GND or V_{CC} , removal of crystal, removal of battery when in the battery backed mode (when a "0" is written to D6), lowering the voltage at the V_{BB} pin to a value less than 2.2V when in the battery backed mode. Bit D6 is automatically set to 1 on initial power-up or an oscillator fail event. The oscillator fail flag is reset by writing a one to the clock start/stop bit in the Real Time Mode Register, with the crystal oscillating.

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the DP8572A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to V_{CC} – 0.4V.

For single supply mode operation, the V_{BB} pin should be connected to GND and the PFAIL pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table III). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

TIME SAVE CONTROL REGISTER

TL/F/9980-14

D0–D4: General purpose RAM bits.

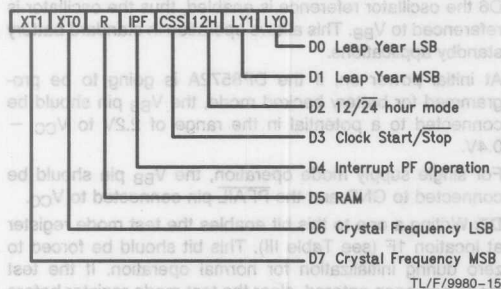

access the registers for up to 480 μ s after it receives a power fail interrupt. After a power failure is detected but prior to the 480 μ s delay timing out, the host μ P may force immediate lock out by resetting the Delay Enable bit. Note if this bit is a 0 when power fails then after a delay of 30 μ s min/63 μ s max the μ P cannot read the chip.

D6: This read only bit is set and reset by the voltage at the V_{BB} pin. It can be used by the μ P to determine whether the battery voltage at the V_{BB} pin is getting too low. A comparator monitors the battery and when the voltage is lower than 2.1V (typical) this bit is set. The power fail interrupt must be enabled to check for a low battery voltage.

D7: Time Save Enable bit controls the loading of real-time-clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

D0–D1: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

D3: This bit is the master Start/Stop bit for the clock. When a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped and the prescaler is cleared. When the RTC is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Note that the MFO pin is configured as open drain in standby mode.

If bit D4 is set to a zero then bits D0–D5 of Interrupt Control Register 0 and bits D6 and D7 of Interrupt Control Register 1 will be reset when the RTC enters the standby mode ($V_{BB} > V_{CC}$). They will have to be re-configured when system (V_{CC}) power is restored.

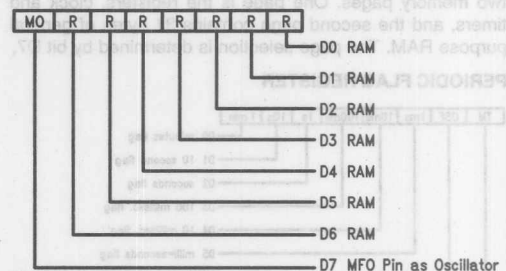

D5: General purpose RAM.

D6 and D7: These two bits select the crystal clock frequency as per the following table:

XT1	XT0	Crystal Frequency
0	0	32.768 kHz
0	1	4.194304 MHz
1	0	4.9152 MHz
1	1	32.000 kHz

All bits are Read/Write, and any mode written into this register can be determined by reading the register. On initial power up these bits are random.

OUTPUT MODE REGISTER

D0–D6: General Purpose RAM

Functional Description (Continued)

D7: This bit is used to program the signal appearing at the MFO output, as follows:

D7	MFO Output Signal
0	Power Fail Interrupt
1	Buffered Crystal Oscillator

INTERRUPT CONTROL REGISTER 0

R R 1m tm hm S TS MN

TL/F/9980-17

D0–D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the periodic time chosen, but after the first interrupt all subsequent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin. If a battery backed mode is selected and the DP8572A is in standby ($V_{BB} > V_{CC}$), then these bits are controlled by D4 of the Real Time Mode Register.

D6 and D7: General Purpose RAM.

INTERRUPT CONTROL REGISTER 1

PFe ALe DOM MO DOM HR MN SC

TL/F/9980-18

D0–D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the “always equal” state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If a battery backed mode is selected and the DP8572A is in standby ($V_{BB} > V_{CC}$), then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when $V_{BB} > V_{CC}$. If a battery backed mode is selected and the DP8572A is in standby ($V_{BB} > V_{CC}$), then this bit is controlled by D4 of the Real Time Mode Register.

This bit also enables the low battery detection analog circuitry.

- ic Flag Register.
- Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
 - Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1,2,3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.
 - After power on (V_{CC} and V_{BB} powered), select the correct crystal frequency bits (D7, D6 in the Real Time Mode Register) as shown in Table IV.

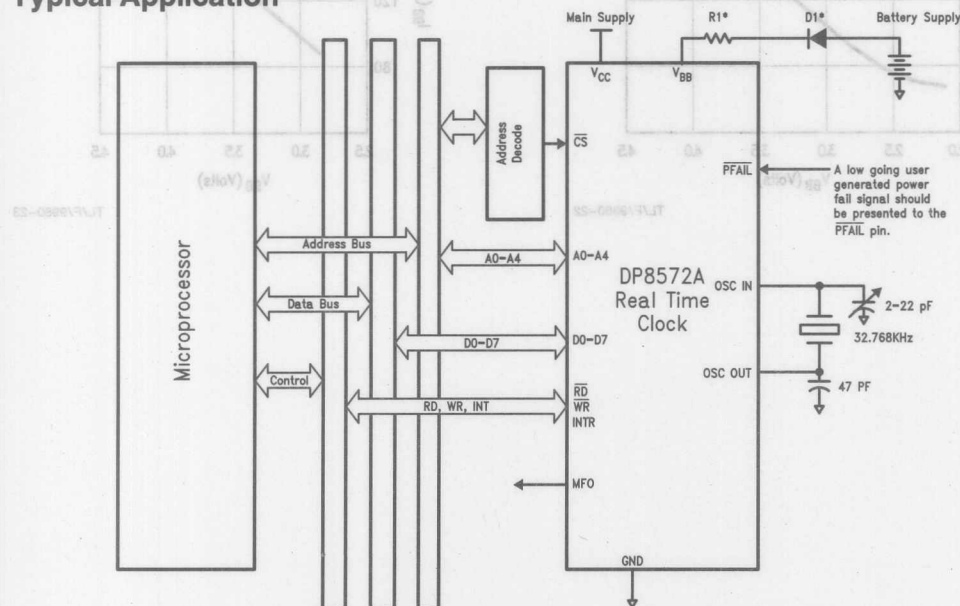

TABLE IV

Frequency	D7	D6
32.768 KHz	0	0
4.194304 MHz	0	1
4.9152 MHz	1	0
32.0 KHz	1	1

- Enter a software loop that does the following:
Set a 3 second(approx) software counter. The crystal oscillator may take 1 second to start.
- Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Make sure the crystal select bits remain the same as in step 1. Under normal operation, this bit can be set only if the oscillator is running. During the

- Test bit D6 in the Periodic Flag Register:
IF a 1, go to 5.1. If this bit remains a 1 after 3 seconds, then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 M Ω .
IF a 0, then the oscillator is running, go to step 7.
- Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the OSC fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder, Bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation.
The only method to ensure the chip is in the battery backed mode is to measure the waveform at the OSC OUT pin. If the battery backed mode was selected successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC} . The measurement should be made with a high impedance low capacitance probe (10 M Ω , 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.
- Write a 1 to bit D7 of Interrupt Control Register 1. This action enables the PFALL pin and associated circuitry.
- Write a 1 to bit D4 of the Real Time Mode Register. This action ensures that bit D7 of Interrupt Control Register 1 remains a 1 when $V_{BB} > V_{CC}$ (Standby Mode).
- Initialize the rest of the chip as needed.

DP8573A Real Time Clock (RTC)

General Description

The DP8573A is intended for use in microprocessor based systems where information is required for multi-tasking, data logging or general time of day/date information. This device is implemented in low voltage silicon gate microCMOS technology to provide low standby power in battery back-up environments. The circuit's architecture is such that it looks like a contiguous block of memory or I/O ports organized as one block of 32 bytes. This includes the Control Registers, the Clock Counters, the Alarm Compare RAM, and the Time Save RAM.

Time and date are maintained from 1/100 of a second to year and leap year in a BCD format, 12 or 24 hour modes. Day of week and day of month counters are provided. Time is controlled by an on-chip crystal oscillator requiring only the addition of the 32.768 kHz crystal and two capacitors.

Power failure logic and control functions have been integrated on chip. This logic is used by the RTC to issue a power fail interrupt, and lock out the μP interface. The time power fails may be logged into RAM automatically when $V_{BB} > V_{CC}$. Additionally, two supply pins are provided. When V_{BB}

> V_{CC} , internal circuitry will automatically switch from the main supply to the battery supply.

The DP8573A's interrupt structure provides three basic types of interrupts: Periodic, Alarm/Compare, and Power Fail. Interrupt mask and status registers enable the masking and easy determination of each interrupt.

Features

- Full function real time clock/calendar
 - 12/24 hour mode timekeeping
 - Day of week counter
 - Parallel resonant oscillator
- Power fail features
 - Internal power supply switch to external battery
 - Power Supply Bus glitch protection
 - Automatic log of time into RAM at power failure
- On-chip interrupt structure
 - Periodic, alarm, and power fail interrupts

Absolute Maximum Ratings (Notes 1 & 2)

If Military/Aerospace specified devices are required, please contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage (V_{CC})	-0.5V to +7.0V
DC Input Voltage (V_{IN})	-0.5V to V_{CC} + 0.5V
DC Output Voltage (V_{OUT})	-0.5V to V_{CC} + 0.5V
Storage Temperature Range	-65°C to +150°C
Power Dissipation (PD)	500 mW
Lead Temperature (Soldering, 10 sec.)	260°C

DC Electrical Characteristics

$V_{CC} = 5V \pm 10\%$, $V_{BB} = 3V$, $V_{PF\text{AIL}} > V_{IH}$, $C_L = 100$ pF (unless otherwise specified)

Symbol	Parameter	Conditions	Min	Max	Units
V_{IH}	High Level Input Voltage (Note 4)	Any Inputs Except OSC IN, OSC IN with External Clock	2.0 $V_{BB} - 0.1$		V
V_{IL}	Low Level Input Voltage	All Inputs Except OSC IN, OSC IN with External Clock		0.8 0.1	V
V_{OH}	High Level Output Voltage (Excluding OSC OUT)	$I_{OUT} = -20 \mu A$ $I_{OUT} = -4.0$ mA	$V_{CC} - 0.1$ 3.5		V
V_{OL}	Low Level Output Voltage (Excluding OSC OUT)	$I_{OUT} = 20 \mu A$ $I_{OUT} = 4.0$ mA		0.1 0.25	V
I_{IN}	Input Current (Except OSC IN)	$V_{IN} = V_{CC}$ or GND		± 1.0	μA
I_{OZ}	Output TRI-STATE® Current	$V_{OUT} = V_{CC}$ or GND		± 5.0	μA
I_{LKG}	Output High Leakage Current T1, MFO, INTR Pins	$V_{OUT} = V_{CC}$ or GND Outputs Open Drain		± 5.0	μA
I_{CC}	Quiescent Supply Current (Note 6)	$F_{OSC} = 32.768$ kHz $V_{IN} = V_{CC}$ or GND (Note 5) $V_{IN} = V_{CC}$ or GND (Note 6) $V_{IN} = V_{IH}$ or V_{IL} (Note 6)		250 1.0 12.0	μA mA mA
I_{CC}	Quiescent Supply Current (Single Supply Mode) (Note 7)	$V_{BB} = \text{GND}$ $V_{IN} = V_{CC}$ or GND $F_{OSC} = 32.768$ kHz		40	μA
I_{BB}	Standby Mode Battery Supply Current (Note 7)	$V_{CC} = \text{GND}$ OSC OUT = open circuit, other pins = GND $F_{OSC} = 32.768$ kHz		10	μA
I_{BLK}	Battery Leakage	$2.2V \leq V_{BB} \leq 4.0V$ other pins at GND $V_{CC} = \text{GND}$ $V_{CC} = 5.5V$	-5	1.5	μA μA

Note 1: Absolute Maximum Ratings are those values beyond which damage to the device may occur.

Note 2: Unless otherwise specified all voltages are referenced to ground.

Note 3: In battery backed mode, $V_{BB} \leq V_{CC} - 0.4V$.

Single Supply Mode: Data retention voltage is 2.2V min.

In single Supply Mode (Power connected to V_{CC} pin) $4.5V \leq V_{CC} \leq 5.5V$.

Note 4: This parameter (V_{IH}) is not tested on all pins at the same time.

Note 5: This specification tests I_{CC} with all power fail circuitry disabled, by setting D7 of Interrupt Control Register 1 to 0.

Note 6: This specification tests I_{CC} with all power fail circuitry enabled, by setting D7 of Interrupt Control Register 1 to 1.

Note 7: OSC IN is driven by a signal generator. Contents of the Test Register = 00(H) and the MFO pin is not configured as buffered oscillator out.

Operation Conditions

	Min	Max	Unit
Supply Voltage (V_{CC}) (Note 3)	4.5	5.5	V
Supply Voltage (V_{BB}) (Note 3)	2.2	$V_{CC} - 0.4$	V

t_{RW}	Read Strobe Width (Note 8)	80		ns
t_{CD}	Chip Select to Data Valid Time		80	ns
t_{RAH}	Address Hold after Read (Note 9)	3		ns
t_{RD}	Read Strobe to Valid Data		70	ns
t_{DZ}	Read or Chip Select to TRI-STATE		60	ns
t_{RCH}	Chip Select Hold after Read Strobe	0		ns
t_{DS}	Minimum Inactive Time between Read or Write Accesses	50		ns
WRITE TIMING				
t_{AW}	Address Valid before Write Strobe	20		ns
t_{WAH}	Address Hold after Write Strobe (Note 9)	3		ns
t_{CW}	Chip Select to End of Write Strobe	90		ns
t_{WW}	Write Strobe Width (Note 10)	80		ns
t_{DW}	Data Valid to End of Write Strobe	50		ns
t_{WDH}	Data Hold after Write Strobe (Note 9)	3		ns
t_{WCH}	Chip Select Hold after Write Strobe	0		ns
INTERRUPT TIMING				
t_{ROLL}	Clock rollover to INTR out typically 16.5 μs			

Note 8: Read Strobe width as used in the read timing table is defined as the period when both chip select and read inputs are low. Hence read commences when both signals are low and terminates when either signal returns high.

Note 9: Hold time is guaranteed by design but not production tested. This limit is not used to calculate outgoing quality levels.

Note 10: Write Strobe width as used in the write timing table is defined as the period when both chip select and write inputs are low. Hence write commences when both signals are low and terminates when either signal returns high.

AC Test Conditions

Input Pulse Levels	GND to 3.0V
Input Rise and Fall Times	6 ns (10%–90%)
Input and Output	1.3V
Reference Levels	
TRI-STATE Reference	Active High +0.5V
Levels (Note 12)	Active Low –0.5V

Note 11: $C_L = 100\text{ pF}$, includes jig and scope capacitance.

Note 12: $S_1 = V_{CC}$ for active low to high impedance measurements.

$S_1 = \text{GND}$ for active high to high impedance measurements.

$S_1 = \text{open}$ for all other timing measurements.

Capacitance ($T_A = 25^\circ\text{C}$, $f = 1\text{ MHz}$)

Symbol	Parameter (Note 14)	Typ	Units
C_{IN}	Input Capacitance	5	pF
C_{OUT}	Output Capacitance	7	pF

Note 13: This parameter is not 100% tested.

Note 14: Output rise and fall times 25 ns max (10%–90%) with 100 pF load.

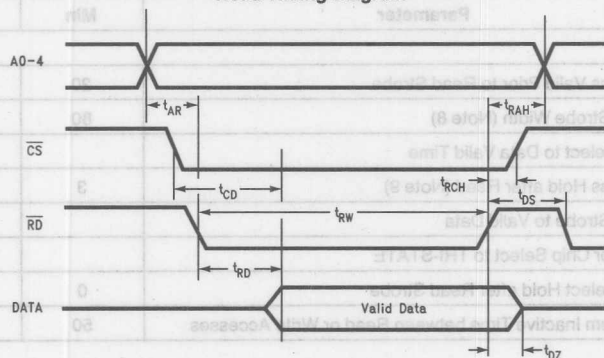

Pin Description: These pins interface to μP control lines. The CS pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the RTC. All three pins are disabled when power failure is detected. However, if a read or write is in progress, this time will be allowed to complete its cycle.

Pin Description

CS, RD, WR (Inputs): These pins interface to μP control lines. The \overline{CS} pin is an active low enable for the read and write operations. Read and Write pins are also active low and enable reading or writing to the RTC. All three pins are disabled when power failure is detected. However, if a read or write is in progress at this time, it will be allowed to complete its cycle.

A0-A4 (Inputs): These 5 pins are for register selection. They individually control which location is to be accessed. These inputs are disabled when power failure is detected.

OSC IN (Input): OSC OUT (Output): These two pins are used to connect the crystal to the internal parallel resonant oscillator. The oscillator is always running when power is applied to V_{BB} and V_{CC} .

MFO (Output): The multi-function output can be used as a second interrupt (Power fail) output for interrupting the μP . This pin can also provide an output for the oscillator. The MFO output is configured as push-pull, active high for normal or single power supply operation and as an open drain during standby mode ($V_{BB} > V_{CC}$). If in battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} .

INTR (Output): The interrupt output is used to interrupt the processor when a timing event or power fail has occurred and the respective interrupt has been enabled. The INTR output is permanently configured active low, open drain. If in

battery backed mode and a pull-up resistor is attached, it should be connected to a voltage no greater than V_{BB} . The output is a DC voltage level. To clear the INTR, write a 1 to the appropriate bit(s) in the Main Status Register.

D0-D7 (Input/Output): These 8 bidirectional pins connect to the host μP 's data bus and are used to read from and write to the RTC. When the PFAIL pin goes low and a write is not in progress, these pins are at TRI-STATE.

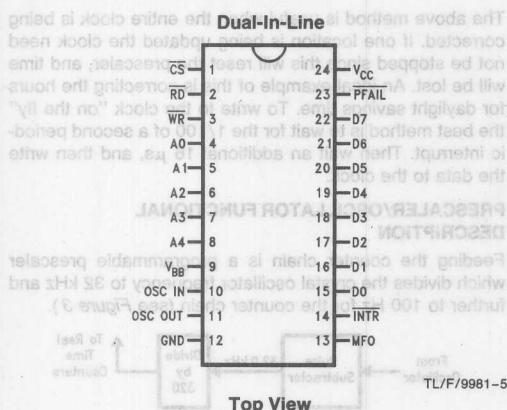

PFail (Input): In battery backed mode, this pin can have a digital signal applied to it via some external power detection logic. When PFAIL = logic 0 the RTC goes into a lockout mode, in a minimum of 30 μs or a maximum of 63 μs unless lockout delay is programmed. In the single power supply mode, this pin is not useable as an input and should be tied to V_{CC} . Refer to section on Power Fail Functional Description.

VBB (Battery Power Pin): This pin is connected to a back-up power supply. This power supply is switched to the internal circuitry when the V_{CC} becomes lower than V_{BB} . Utilizing this pin eliminates the need for external logic to switch in and out the back-up power supply. If this feature is not to be used then this pin must be tied to ground, the RTC programmed for single power supply only, and power applied to the V_{CC} pin.

VCC: This is the main system power pin.

GND: This is the common ground power pin for both V_{BB} and V_{CC} .

Functional Description

The DP8573A contains a fast access real time clock, interrupt control logic, and power fail detect logic. All functions of the RTC are controlled by a set of seven registers. A simplified block diagram that shows the major functional blocks is given in Figure 1.

The blocks are described in the following sections:

1. Real Time Clock
2. Oscillator Prescaler
3. Interrupt Logic
4. Power Failure Logic
5. Additional Supply Management

The memory map of the RTC is shown in the memory addressing table (Figure 2). A control bit in the Main Status Register is used to select either control register block.

INITIAL POWER-ON of BOTH V_{BB} and V_{CC}

V_{BB} and V_{CC} may be applied in any sequence. In order for the power fail circuitry to function correctly, whenever power is off, the V_{CC} pin must see a path to ground through a maximum of 1 M Ω . The user should be aware that the control registers will contain random data. The user should ensure that the RTC is not in test mode (see register descriptions).

REAL TIME CLOCK FUNCTIONAL DESCRIPTION

As shown in Figure 2, the clock has 8 bytes of counters, which count from 1/100 of a second to years. Each counter counts in BCD and is synchronously clocked. The count sequence of the individual byte counters within the clock is shown later in Table VII. Note that the day of week, day of month, and month counters all roll over to 1. The hours counter in 12 hour mode rolls over to 1 and the AM/PM bit toggles when the hours rolls over to 12 (AM = 0, PM = 1). The AM/PM bit is bit D7 in the hours counter.

All other counters roll over to 0. Upon initial application of power the counters will contain random information.

TL/F/9981-7

reading of the counter, it is possible to read the counter while it is being incremented (rollover). This may result in an incorrect time reading. Thus to ensure a correct reading of the entire contents of the clock (or that part of interest), it must be read without a clock rollover occurring. In general this can be done by checking a rollover bit. On this chip the periodic interrupt status bits can serve this function. The following program steps can be used to accomplish this.

1. Initialize program for reading clock.
2. Dummy read of periodic status bit to clear it.
3. Read counter bytes and store.
4. Read rollover bit, and test it.
5. If rollover occurred go to 3.
6. If no rollover, done.

To detect the rollover, individual periodic status bits can be polled. The periodic bit chosen should be equal to the highest frequency counter register to be read. That is if only SECONDS through HOURS counters are read, then the SECONDS periodic bit should be used.

READING THE CLOCK: INTERRUPT DRIVEN

Enabling the periodic interrupt mask bits cause interrupts just as the clock rolls over. Enabling the desired update rate and providing an interrupt service routine that executes in less than 10 ms enables clock reading without checking for a rollover.

READING THE CLOCK: LATCHED READ

Another method to read the clock that does not require checking the rollover bit is to write a one into the Time Save Enable bit (D7) of the Time Save Control Register, and then to write a zero. Writing a one into this bit will enable the clock contents to be duplicated in the Time Save RAM. Changing the bit from a one to a zero will freeze and store the contents of the clock in Time Save RAM. The time then can be read without concern for clock rollover, since internal logic takes care of synchronization of the clock. Because only the bits used by the clock counters will be latched, the Time Save RAM should be cleared prior to use to ensure that random data stored in the unused bits do not confuse the host microprocessor. This bit can also provide time save at power failure, see the Additional Supply Management Functions section. With the Time Save Enable bit at a logical 0, the Time Save RAM may be used as RAM if the latched read function is not necessary.

INITIALIZING AND WRITING TO THE CALENDAR-CLOCK

Upon initial application of power to the TCP or when making time corrections, the time must be written into the clock. To correctly write the time to the counters, the clock would normally be stopped by writing the Start/Stop bit in the Real Time Mode Register to a zero. This stops the clock from counting and disables the carry circuitry. When initializing the clock's Real Time Mode Register, it is recommended that first the various mode bits be written while maintaining the Start/Stop bit reset, and then writing to the register a second time with the Start/Stop bit set.

not be stopped since this will reset the prescaler, and time will be lost. An ideal example of this is correcting the hours for daylight savings time. To write to the clock "on the fly" the best method is to wait for the 1/100 of a second periodic interrupt. Then wait an additional 16 μ s, and then write the data to the clock.

PRESCALER/OSCILLATOR FUNCTIONAL DESCRIPTION

Feeding the counter chain is a programmable prescaler which divides the crystal oscillator frequency to 32 kHz and further to 100 Hz for the counter chain (see Figure 3).

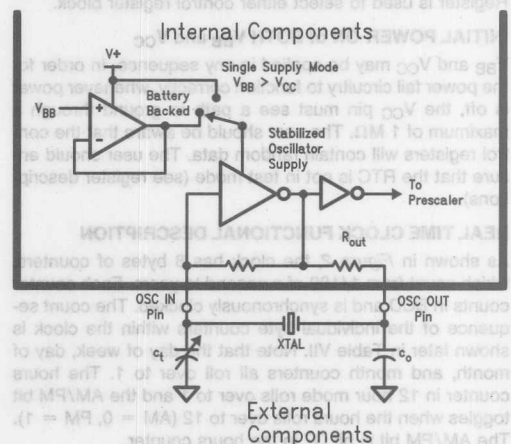

TL/F/9981-8

FIGURE 3. Programmable Clock Prescaler Block

In addition to the inverter, the oscillator feedback bias resistor is included on chip, as shown in Figure 4. The oscillator input may be driven from an external source if desired. Refer to test mode application note for details. The oscillator stability is enhanced through the use of an on chip regulated power supply.

The typical range of trimmer capacitor (as shown in Oscillator Circuit Diagram Figure 4, and in the typical application) at the oscillator input pin is suggested only to allow accurate tuning of the oscillator. This range is based on a typical printed circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases, the load capacitance specified by the crystal manufacturer (nominal value 11 pF for the 32.768 crystal) is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal (with respect to ground).

TL/F/9981-9

FIGURE 4. Oscillator Circuit Diagram

INTERRUPT LOGIC FUNCTIONAL DESCRIPTION

The RTC has the ability to coordinate processor timing activities. To enhance this, an interrupt structure has been implemented which enables several types of events to cause interrupts. Interrupts are controlled via two Control Registers in block 1 and two Status Registers in block 0. (See Register Description for notes on paging and Table I.)

The interrupts are enabled by writing a one to the appropriate bits in Interrupt Control Register 0 and/or 1.

TABLE I. Registers that are Applicable to Interrupt Control

Register Name	Register Select	Address
Main Status Register	X	00H
Periodic Flag Register	0	03H
Interrupt Control Register 0	1	03H
Interrupt Control Register 1	1	04H
Output Mode Register	1	02H

The Interrupt Status Flag D0, in the Main Status Register, indicates the state of INTR and MFO outputs. It is set when either output becomes active and is cleared when all RTC interrupts have been cleared and no further interrupts are pending (i.e., both INTR and MFO are returned to their inactive state). This flag enables the RTC to be rapidly polled by the μ P to determine the source of an interrupt in a wired-OR interrupt system. (The Interrupt Status Flag provides a true reflection of all conditions routed to the external pins.) Status for the interrupts are provided by the Main Status Register and the Periodic Flag Register. Bits D1-D5 of the Main Status Register are the main interrupt bits.

These register bits will be set when their associated timing events occur. Enabled Alarm comparisons that occur will set its Main Status Register bit to a one. However, an external interrupt will only be generated if the Alarm interrupt enable bit is set (see *Figure 5*).

Disabling the periodic interrupts will mask the Main Status Register periodic bit, but not the Periodic Flag Register bits. The Power Fail Interrupt bit is set when the interrupt is enabled and a power fail event has occurred, and is not reset until the power is restored. If all interrupt enable bits are 0 no interrupt will be asserted. However, status still can be read from the Main Status Register in a polled fashion (see *Figure 5*).

To clear a flag in bits D2 and D3 of the Main Status Register a 1 must be written back into the bit location that is to be cleared. For the Periodic Flag Register reading the status will reset all the periodic flags.

Interrupts Fall Into Three Categories:

1. The Alarm Compare Interrupt: Issued when the value in the time compared RAM equals the counter.
2. The Periodic Interrupts: These are issued at every increment of the specific clock counter signal. Thus, an interrupt is issued every minute, second, etc. Each of these interrupts occurs at the roll-over of the specific counter.

power failed condition is determined by the signal on the PFAIL pin. The internal power fail signal is gated with the chip select signal to ensure that the power fail interrupt does not lock the chip out during a read or write.

ALARM COMPARE INTERRUPT DESCRIPTION

The alarm/time comparison interrupt is a special interrupt similar to an alarm clock wake up buzzer. This interrupt is generated when the clock time is equal to a value programmed into the alarm compare registers. Up to six bytes can be enabled to perform alarm time comparisons on the counter chain. These six bytes, or some subset thereof, would be loaded with the future time at which the interrupt will occur. Next, the appropriate bits in the Interrupt Control Register 1 are enabled or disabled (refer to detailed description of Interrupt Control Register 1). The RTC then compares these bytes with the clock time. When all the enabled compare registers equal the clock time an alarm interrupt is issued, but only if the alarm compare interrupt is enabled can the interrupt be generated externally. Each alarm compare bit in the Control Register will enable a specific byte for comparison to the clock. Disabling a compare byte is the same as setting its associated counter comparator to an "always equal" state. For example, to generate an interrupt at 3:15 AM of every day, load the hours compare with 0 3 (BCD), the minutes compare with 1 5 (BCD) and the faster counters with 0 0 (BCD), and then disable all other compare registers. So every day when the time rolls over from 3:14:59.99, an interrupt is issued. This bit may be reset by writing a one to bit D3 in the Main Status Register at any time after the alarm has been generated.

If time comparison for an individual byte counter is disabled, that corresponding RAM location can then be used as general purpose storage.

PERIODIC INTERRUPTS DESCRIPTION

The Periodic Flag Register contains six flags which are set by real-time generated "ticks" at various time intervals, see *Figure 5*. These flags constantly sense the periodic signals and may be used whether or not interrupts are enabled. These flags are cleared by any read or write operation performed on this register.

To generate periodic interrupts at the desired rate, the associated Periodic Interrupt Enable bit in Interrupt Control Register 0 must be set. Any combination of periodic interrupts may be enabled to operate simultaneously. Enabled periodic interrupts will now affect the Periodic Interrupt Flag in the Main Status Register.

When a periodic event occurs, the Periodic Interrupt Flag in the Main Status Register is set, causing an interrupt to be generated. The μ P clears both flag and interrupt by writing a "1" to the Periodic Interrupt Flag. The individual flags in the periodic Interrupt Flag Register do not require clearing to cancel the interrupt.

If all periodic interrupts are disabled and a periodic interrupt is left pending (i.e., the Periodic Interrupt Flag is still set), the Periodic Interrupt Flag will still be required to be cleared to cancel the pending interrupt.

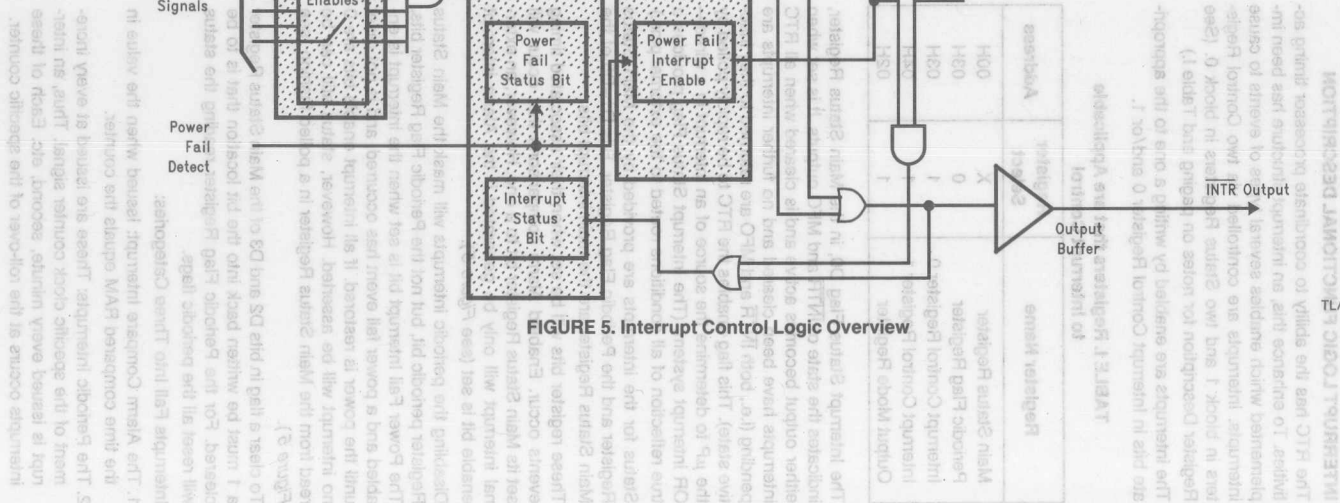

FIGURE 5. Interrupt Control Logic Overview

Functional Description (Continued)

POWER FAIL INTERRUPTS DESCRIPTION

The Power Fail Status Flag in the Main Status Register monitors the state of the internal power fail signal. This flag may be interrogated by the μP , but it cannot be cleared; it is cleared automatically by the RTC when system power is restored. To generate an interrupt when the power fails, the Power Fail Interrupt Enable bit in Interrupt Control Register 1 is set. Although this interrupt may not be cleared, it may be masked by clearing the Power Fail Interrupt Enable bit.

POWER FAILURE CIRCUITRY FUNCTIONAL DESCRIPTION

Since the clock must be operated from a battery when the main system supply has been turned off, the DP8573A provides circuitry to simplify design in battery backed systems. This switches over to the back up supply, and isolates itself from the host system. Figure 6 shows a simplified block diagram of this circuitry, which consists of three major sections; 1) power loss logic; 2) battery switch over logic; and 3) isolation logic.

Detection of power loss occurs when \overline{PFAIL} is low. De-bounce logic provides a 30 μs –63 μs debounce time, which will prevent noise on the \overline{PFAIL} pin from being interpreted as a system failure. After 30 μs –63 μs the debounce logic times out and a signal is generated indicating that system power is marginal and is failing. The Power Fail Interrupt will then be generated.

If chip select is low when a power failure is detected, a safety circuit will ensure that if a read or write is held active continuously for greater than 30 μs after the power fail signal is asserted, the lock-out will be forced.

The battery switch over circuitry is completely independent of the \overline{PFAIL} pin. A separate circuit compares V_{CC} to the V_{BB} voltage. As the main supply fails, the RTC will continue to operate from the V_{CC} pin until V_{CC} falls below the V_{BB} voltage. At this time, the battery supply is switched in, V_{CC} is

disconnected, and the device is now in the standby mode. If indeterminate operation of the battery switch over circuit is to be avoided, then the voltage at the V_{CC} pin must not be allowed to equal the voltage at the V_{BB} pin.

After the generation of a lock-out signal, and eventual switch in of the battery supply, the pins of the RTC will be configured as shown in Table II. Outputs that have a pull-up resistor should be connected to a voltage no greater than V_{BB} .

TABLE II. Pin Isolation during a Power Failure

Pin	\overline{PFAIL} = Logic 0	Standby Mode $V_{BB} > V_{CC}$
\overline{CS} , \overline{RD} , \overline{WR}	Locked Out	Locked Out
A0–A4	Locked Out	Locked Out
D0–D7	Locked Out	Locked Out
Oscillator	Not Isolated	Not Isolated
\overline{PFAIL}	Not Isolated	Not Isolated
INTR, MFO	Not Isolated	Open Drain

The Interrupt Power Fail Operation bit in the Real-Time Mode Register determines whether or not the interrupts will continue to function after a power fail event.

As power returns to the system, the battery switch over circuit will switch back to V_{CC} power as soon as it becomes greater than the battery voltage. The chip will remain in the locked out state as long as $\overline{PFAIL} = 0$. When $\overline{PFAIL} = 1$ the chip is unlocked, but only after another 30 μs min. \rightarrow 63 μs max debounce time. The system designer must ensure that his system is stable when power has returned.

The power fail circuitry contains active linear circuitry that draws supply current from V_{CC} . In some cases this may be undesirable, so this circuit can be disabled by masking the power fail interrupt. The power fail input can perform all lock-out functions previously mentioned, except that no ex-

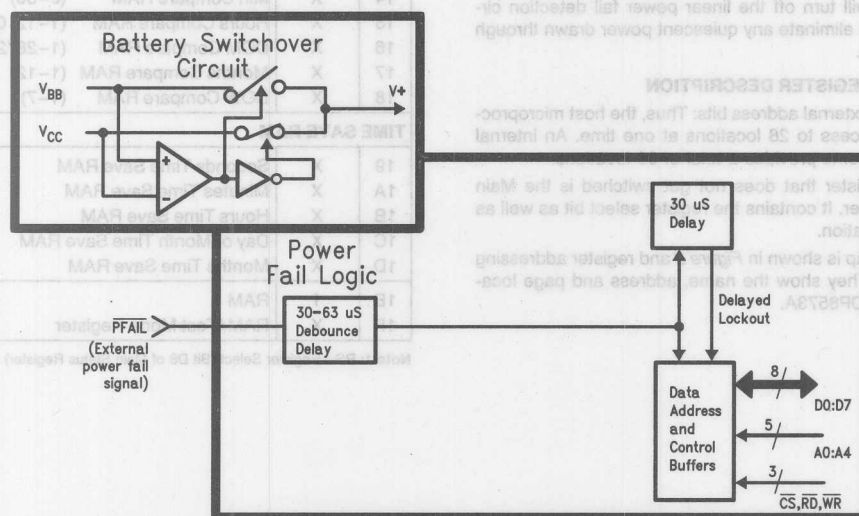

FIGURE 6. System-Battery Switchover (Upper Left), Power Fail and Lock-Out Circuits (Lower Right)

TL/F/9981-11

INITIAL POWER ON DETECT AND POWER FAIL TIME SAVE

There are two other functions provided on the DP8573A to ease power supply control. These are an initial Power On detect circuit, which also can be used as a time keeping failure detect, and a time save on power failure.

On initial power up the Oscillator Fail Flag will be set to a one and the real time clock start bit reset to a zero. This indicates that an oscillator fail event has occurred, and time keeping has failed.

The Oscillator Fail flag will not be reset until the real-time clock is started. This allows the system to discriminate between an initial power-up and recovery from a power failure. If the battery backed mode is selected, then bit D6 of the Periodic Flag Register must be written low. This will not affect the contents of the Oscillator Fail Flag.

To relieve CPU overhead for saving time upon power failure, the Time Save Enable bit is provided to do this automatically. (See also Reading the Clock: Latched Read.) The Time Save Enable bit, when set, causes the Time Save RAM to follow the contents of the clock. This bit can be reset by software, but if set before a power failure occurs, it will automatically be reset when the clock switches to the battery supply (not when a power failure is detected by the PFAIL pin). Thus, writing a one to the Time Save bit enables both a software write or power fail write.

SINGLE POWER SUPPLY APPLICATIONS

The DP8573A can be used in a single power supply application. To achieve this, the V_{BB} pin must be connected to ground, and the power connected to V_{CC}. The Oscillator Failed/Single Supply bit in the Periodic Flag Register should be set to a logic 1, which will disable the oscillator battery reference circuit. The power fail interrupt should also be disabled. This will turn off the linear power fail detection circuits, and will eliminate any quiescent power drawn through these circuits.

DETAILED REGISTER DESCRIPTION

There are 5 external address bits: Thus, the host microprocessor has access to 28 locations at one time. An internal switching scheme provides a total of 30 locations.

The only register that does not get switched is the Main Status Register. It contains the register select bit as well as status information.

A memory map is shown in Figure 2 and register addressing in Table III. They show the name, address and page locations for the DP8573A.

Note 1: RS—Register Select (Bit D6 of Main Status Register)

Functional Description (Continued)

MAIN STATUS REGISTER

The Main Status Register is always located at address 0 regardless of the register block selected.

D0: This read only bit is a general interrupt status bit that is taken directly from the interrupt pins. The bit is a one when an interrupt is pending on either the INTR pin or the MFO pin (when configured as an interrupt). This is unlike D3 which can be set by an internal event but may not cause an interrupt. This bit is reset when the interrupt status bits in the Main Status Register are cleared.

D1-D3: These three bits of the Main Status Register are the main interrupt status bits. Any bit may be a one when any of the interrupts are pending. Once an interrupt is asserted the μP will read this register to determine the cause. These interrupt status bits are not reset when read. Except for D1, to reset an interrupt a one is written back to the corresponding bit that is being tested. D1 is reset whenever the PFALL pin = logic 1. This prevents loss of interrupt status when reading the register in a polled mode. D1 and D3 are set regardless of whether these interrupts are masked or not by bits D6 and D7 of Interrupt Control Registers 0 and 1.

D4, D5 and D7: General purpose RAM bits.

D6: Bit D6 controls the register block to be accessed (see memory map).

PERIODIC FLAG REGISTER

The Periodic Flag Register has the same bit for bit correspondence as Interrupt Control Register 0 except for D6 and D7. For normal operation (i.e., not a single supply application) this register must be written to on initial power up or after an oscillator fail event. D0-D5 are read only bits, D6 and D7 are read/write.

D0-D5: These bits are set by the real time rollover events: (Time Change = 1). The bits are reset when the register is read and can be used as selective data change flags.

D6: This bit performs a dual function. When this bit is read, a one indicates that an oscillator failure has occurred and the time information may have been lost. Some of the ways an oscillator failure might be caused are: failure of the crystal, shorting OSC IN or OSC OUT to GND or V_{CC} , removal of crystal, removal of battery when in the battery backed mode (when a "0" is written to D6), lowering the voltage at the V_{BB} pin to a value less than 2.2V when in the battery

backed mode. Bit D6 is automatically set to 1 on initial power-up or an oscillator fail event. The oscillator fail flag is reset by writing a one to the clock start/stop bit in the Real Time Mode Register, with the crystal oscillating.

When D6 is written to, it defines whether the TCP is being used in battery backed (normal) or in a single supply mode application. When set to a one this bit configures the TCP for single power supply applications. This bit is automatically set on initial power-up or an oscillator fail event. When set, D6 disables the oscillator reference circuit. The result is that the oscillator is referenced to V_{CC} . When a zero is written to D6 the oscillator reference is enabled, thus the oscillator is referenced to V_{BB} . This allows operation in standard battery standby applications.

At initial power on, if the DP8573A is going to be programmed for battery backed mode, the V_{BB} pin should be connected to a potential in the range of 2.2V to V_{CC} - 0.4V.

For single supply mode operation, the V_{BB} pin should be connected to GND and the PFALL pin connected to V_{CC} .

D7: Writing a one to this bit enables the test mode register at location 1F (see Table III). This bit should be forced to zero during initialization for normal operation. If the test mode has been entered, clear the test mode register before leaving test mode. (See separate test mode application note for further details.)

TIME SAVE CONTROL REGISTER

D0-D5: General purpose RAM bits.

D6: Not Available, appears as logic 0 when read.

D7: Time Save Enable bit controls the loading of real-time-clock data into the Time Save RAM. When a one is written to this bit the Time Save RAM will follow the corresponding clock registers, and when a zero is written to this bit the time in the Time Save RAM is frozen. This eliminates any synchronization problems when reading the clock, thus negating the need to check for a counter rollover during a read cycle.

This bit must be set to a one prior to power failing to enable the Time Save feature. When the power fails this bit is automatically reset and the time is saved in the Time Save RAM.

REAL TIME MODE REGISTER

Functional Description (Continued)

D0–D1: These are the leap year counter bits. These bits are written to set the number of years from the previous leap year. The leap year counter increments on December 31st and it internally enables the February 29th counter state. This method of setting the leap year allows leap year to occur whenever the user wishes to, thus providing flexibility in implementing Japanese leap year function.

LY1	LY0	Leap Year Counter
0	0	Leap Year Current Year
0	1	Leap Year Last Year
1	0	Leap Year 2 Years Ago
1	1	Leap Year 3 Years Ago

D2: The count mode for the hours counter can be set to either 24 hour mode or 12 hour mode with AM/PM indicator. A one will place the clock in 12 hour mode.

D3: This bit is the master Start/Stop bit for the clock. When a one is written to this bit the real time counter's prescaler and counter chain are enabled. When this bit is reset to zero the contents of the real time counter is stopped. When the RTC is initially powered up this bit will be held at a logic 0 until the oscillator starts functioning correctly after which this bit may be modified. If an oscillator fail event occurs, this bit will be reset to logic 0.

D4: This bit controls the operation of the interrupt output in standby mode. If set to a one it allows Alarm, Periodic, and Power Fail interrupts to be functional in standby mode. Note that the MFO pin is configured as open drain in standby mode.

If bit D4 is set to a zero then bits D0–D5 of Interrupt Control Register 0 and bits D6 and D7 of Interrupt Control Register 1 will be reset when the RTC enters the standby mode. They will have to be re-configured when system (V_{CC}) power is restored.

D5–D7: General purpose RAM bits.

OUTPUT MODE REGISTER

D0–D6: General purpose RAM bits.

D7: This bit is used to program the signal appearing at the MFO output, as follows:

D7	MFO Output Signal
0	Power Fail Interrupt
1	Buffered Crystal Oscillator

INTERRUPT CONTROL REGISTER 0

D0–D5: These bits are used to enable one of the selected periodic interrupts by writing a one into the appropriate bit. These interrupts are issued at the rollover of the clock. For example, the minutes interrupt will be issued whenever the minutes counter increments. In all likelihood the interrupt will be enabled asynchronously with the real time change. Therefore, the very first interrupt will occur in less than the periodic time chosen, but after the first interrupt all subsequent interrupts will be spaced correctly. These interrupts are useful when minute, second, real time reading, or task switching is required. When all six bits are written to a 0 this disables periodic interrupts from the Main Status Register and the interrupt pin. If battery backed mode is selected and the DP8573A is in standby ($V_{BB} > V_{CC}$), then these bits are controlled by D4 of the Real Time Mode Register.

D6 and D7: General purpose RAM.

INTERRUPT CONTROL REGISTER 1

D0–D5: Each of these bits are enable bits which will enable a comparison between an individual clock counter and its associated compare RAM. If any bit is a zero then that clock-RAM comparator is set to the "always equal" state and the associated TIME COMPARE RAM byte can be used as general purpose RAM. However, to ensure that an alarm interrupt is not generated at bit D3 of the Main Status Register, all bits must be written to a logic zero.

D6: In order to generate an external alarm compare interrupt to the μP from bit D3 of the Main Status Register, this bit must be written to a logic 1. If battery backed mode is selected and the DP8573A is in standby ($V_{BB} > V_{CC}$), then this bit is controlled by D4 of the Real Time Mode Register.

D7: The MSB of this register is the enable bit for the Power Fail Interrupt. When this bit is set to a one an interrupt will be generated to the μP when $V_{BB} > V_{CC}$. If battery backed mode is selected and the DP8573A is in standby ($V_{BB} > V_{CC}$), then this bit is controlled by D4 of the Real Time Mode Register.

Application Hints

Suggested Initialization Procedure for DP8573A in Battery Backed Applications that use the V_{BB} Pin

1. Enter the test mode by writing a 1 to bit D7 in the Periodic Flag Register.
2. Write zero to the RAM/TEST mode Register located in page 0, address HEX 1F.
3. Leave the test mode by writing a 0 to bit D7 in the Periodic Flag Register. Steps 1, 2, 3 guarantee that if the test mode had been entered during power on (due to random pulses from the system), all test mode conditions are cleared. Most important is that the OSC Fail Disable bit is cleared. Refer to AN-589 for more information on test mode operation.

4. Enter a software loop that does the following:
Set a 3 second(approx) software counter. The crystal oscillator may take 1 second to start.
- 4.1 Write a 1 to bit D3 in the Real Time Mode Register (try to start the clock). Under normal operation, this bit can be set only if the oscillator is running. During the software loop, RAM, real time counters, output configuration, interrupt control and timer functions may be initialized.

1. Reset by writing 1 to bit.
2. Set/reset by voltage at PFAIL pin.
3. Reset when all pending interrupts are removed.
4. Read Osc fail Write 0 Batt-Backed Mode Write 1 Single Supply Mode
5. Reset by positive edge of read.

then abort and check hardware. The crystal may be defective or not installed. There may be a short at OSC IN or OSC OUT to V_{CC} or GND, or to some impedance that is less than 10 M Ω .

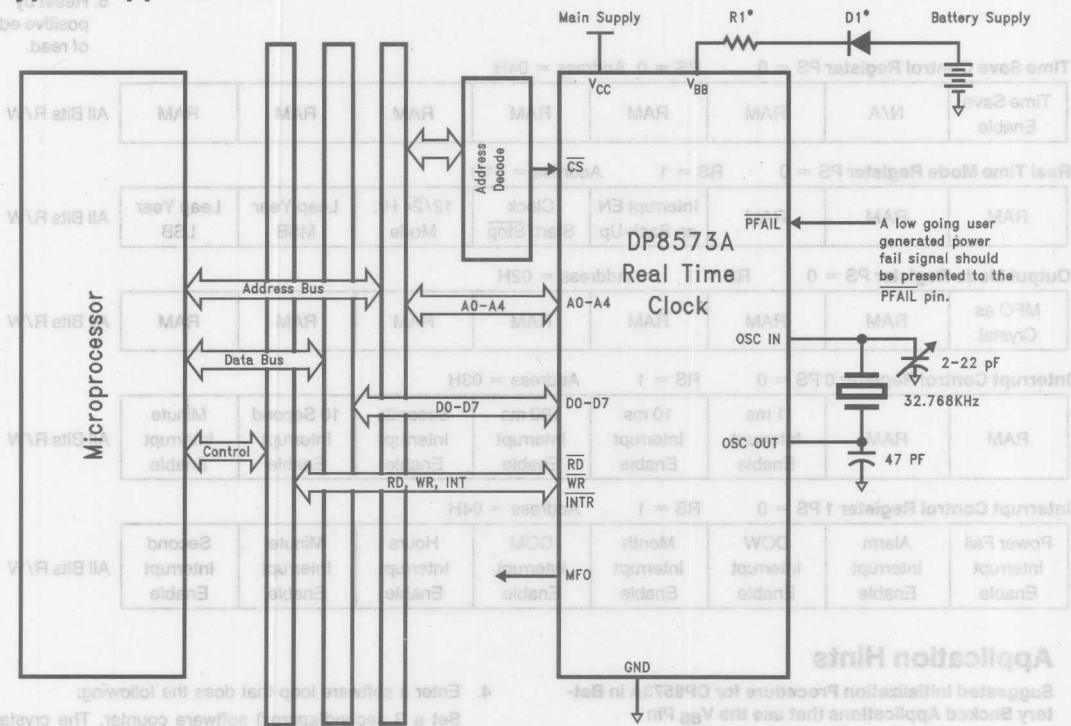

IF a 0, then the oscillator is running, go to step 7.

- Write a 0 to bit D6 in the Periodic Flag Register. This action puts the clock chip in the battery backed mode. This mode can be entered only if the OSC fail flag (bit D6 of the Periodic Flag Register) is a 0. Reminder, bit D6 is a dual function bit. When read, D6 returns oscillator status. When written, D6 causes either the Battery Backed Mode, or the Single Supply Mode of operation.

successfully, then the peak to peak waveform at OSC OUT is referenced to the battery voltage. If not in battery backed mode, the waveform is referenced to V_{CC} . The measurement should be made with a high impedance low capacitance probe (10 M Ω , 10 pF oscilloscope probe or better). Typical peak to peak swings are within 0.6V of V_{CC} and ground respectively.

- Write a 1 to bit D7 of Interrupt Control Register 1. This action enables the PFAIL pin and associated circuitry.
- Write a 1 to bit D4 of the Real Time Mode Register. This action ensures that bit D7 of Interrupt Control Register 1 remains a 1 when $V_{BB} > V_{CC}$ (Standby Mode).
- Initialize the rest of the chip as needed.

Typical Application

*These components may be necessary to meet UL requirements for lithium batteries. Consult battery manufacturer.

MM58274C-12

Microprocessor Compatible Real Time Clock

General Description

The MM58274C-12 is fabricated using low threshold metal gate CMOS technology and is designed to operate in bus oriented microprocessor systems where a real time clock and calendar function are required. The on-chip 32.768 kHz crystal controlled oscillator will maintain timekeeping down to 2.2V to allow low power standby battery operation. This device is pin compatible with the MM58174A but continues timekeeping up to tens of years.

Applications

- Point of sale terminals
- Teller terminals
- Word processors
- Data logging
- Industrial process control

Features

- Same pin-out as MM58174A, MM58274B, MM58274C, and MM58274
- Timekeeping from tenths of seconds to tens of years in independently accessible registers
- Leap year register
- 12 hour operation only
- Buffered crystal frequency output in test mode for easy oscillator setting
- Data-changed flag allows simple testing for time rollover
- Independent interrupting time with open drain output
- Fully TTL compatible
- Low power standby operation (10 μ A at 2.2V)
- Low cost 16-pin DIP and 20-pin PCC

t _{WD}	Data Bus Hold Time Following Write Strobe 	100	35		ns
t _{AWS}	Address Bus Valid Before Start of Write Strobe	70	20		ns

Note 3: Except for special case restriction: with interrupts programmed, max read strobe width of control register (ADDR 0) is 30 ms. See section on Interrupt Programming.

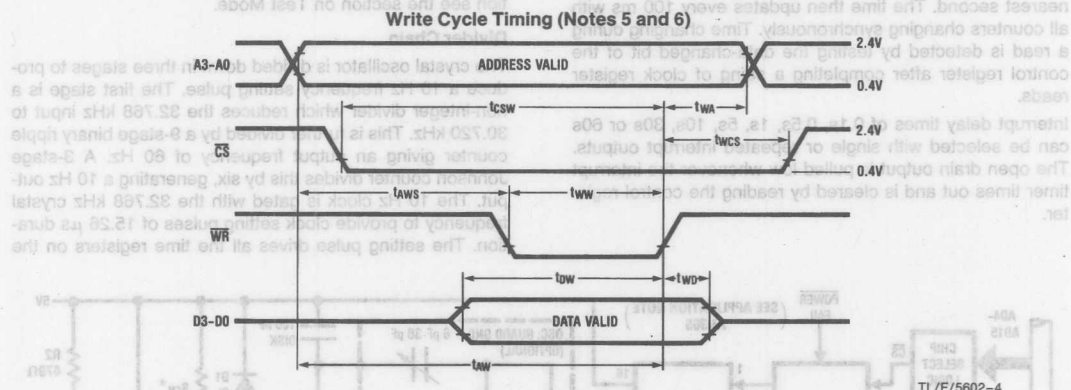

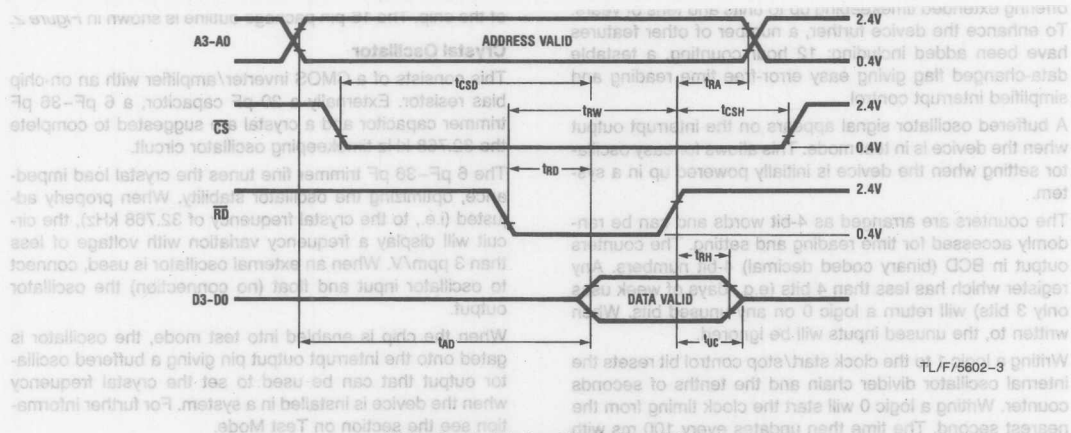

Note 4: All timings measured to the trailing edge of write strobe (data latched by the trailing edge of WR).

Note 5: Input test waveform peak voltages are 2.4V and 0.4V. Output signals are measured to their 2.4V and 0.4V levels.

Note 6: Write strobe as used in the Write Timing Table is defined as the period when both chip select and write inputs are low, i.e., $WS = \overline{CS} + \overline{WR}$. Hence write strobe commences when both signals are low, and terminates when the first signal returns high.

Note 7: Read strobe as used in the Read Timing Table is defined as the period when both chip select and read inputs are low, i.e., $RS = \overline{CS} + \overline{RD}$.

Note 8: Typical numbers are at $V_{CC} = 5.0V$ and $T_A = 25^\circ\text{C}$.

Connection Diagrams

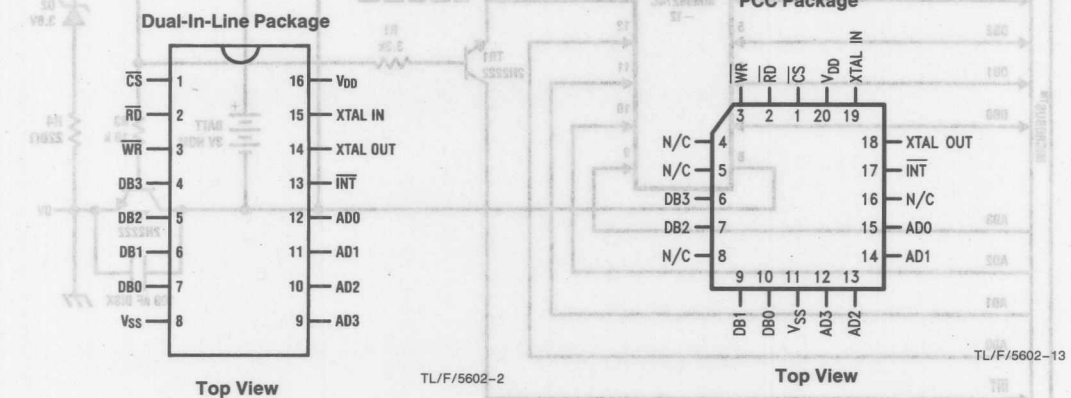

FIGURE 2

Order Number MM58274CJ-12, MM58274CN-12 or MM58274CV-12
See NS Package J16A, N16A, or V20A

Functional Description

The MM58274C-12 is a bus oriented microprocessor real time clock. It has the same pin-out as the MM58174A while offering extended timekeeping up to units and tens of years. To enhance the device further, a number of other features have been added including: 12 hour counting, a testable data-changed flag giving easy error-free time reading and simplified interrupt control.

A buffered oscillator signal appears on the interrupt output when the device is in test mode. This allows for easy oscillator setting when the device is initially powered up in a system.

The counters are arranged as 4-bit words and can be randomly accessed for time reading and setting. The counters output in BCD (binary coded decimal) 4-bit numbers. Any register which has less than 4 bits (e.g., days of week uses only 3 bits) will return a logic 0 on any unused bits. When written to, the unused inputs will be ignored.

Writing a logic 1 to the clock start/stop control bit resets the internal oscillator divider chain and the tenths of seconds counter. Writing a logic 0 will start the clock timing from the nearest second. The time then updates every 100 ms with all counters changing synchronously. Time changing during a read is detected by testing the data-changed bit of the control register after completing a string of clock register reads.

Interrupt delay times of 0.1s, 0.5s, 1s, 5s, 10s, 30s or 60s can be selected with single or repeated interrupt outputs. The open drain output is pulled low whenever the interrupt timer times out and is cleared by reading the control register.

CIRCUIT DESCRIPTION

The block diagram in Figure 1 shows the internal structure of the chip. The 16-pin package outline is shown in Figure 2.

Crystal Oscillator

This consists of a CMOS inverter/amplifier with an on-chip bias resistor. Externally a 20 pF capacitor, a 6 pF–36 pF trimmer capacitor and a crystal are suggested to complete the 32.768 kHz timekeeping oscillator circuit.

The 6 pF–36 pF trimmer fine tunes the crystal load impedance, optimizing the oscillator stability. When properly adjusted (i.e., to the crystal frequency of 32.768 kHz), the circuit will display a frequency variation with voltage of less than 3 ppm/V. When an external oscillator is used, connect to oscillator input and float (no connection) the oscillator output.

When the chip is enabled into test mode, the oscillator is gated onto the interrupt output pin giving a buffered oscillator output that can be used to set the crystal frequency when the device is installed in a system. For further information see the section on Test Mode.

Divider Chain

The crystal oscillator is divided down in three stages to produce a 10 Hz frequency setting pulse. The first stage is a non-integer divider which reduces the 32.768 kHz input to 30.720 kHz. This is further divided by a 9-stage binary ripple counter giving an output frequency of 60 Hz. A 3-stage Johnson counter divides this by six, generating a 10 Hz output. The 10 Hz clock is gated with the 32.768 kHz crystal frequency to provide clock setting pulses of 15.26 μ s duration. The setting pulse drives all the time registers on the

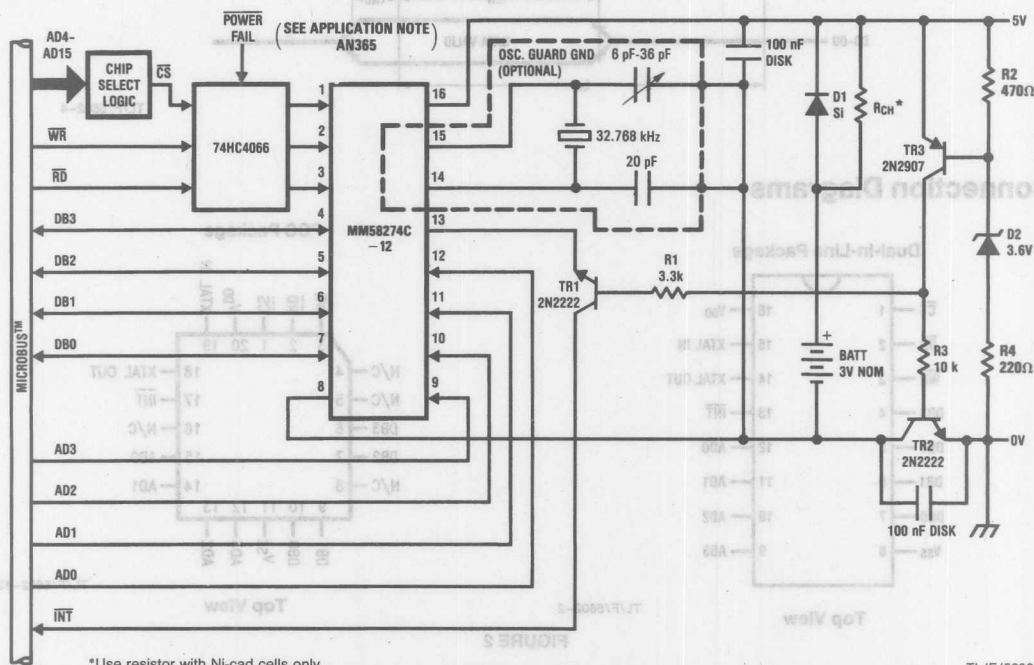

FIGURE 3. Typical System Connection Diagram

TL/F/5602-5

Functional Description (Continued)

device which are synchronously clocked by this signal. All time data and data-changed flag change on the falling edge of the clock setting pulse.

Data-Changed Flag

The data-changed flag is set by the clock setting pulse to indicate that the time data has been altered since the clock was last read. This flag occupies bit 3 of the control register where it can be tested by the processor to sense data-changed. It will be reset by a read of the control register. See the section, "Methods of Device Operation", for suggested clock reading techniques using this flag.

Seconds Counters

There are three counters for seconds:

- tenths of seconds
- units of seconds
- tens of seconds

The registers are accessed at the addresses shown in Table I. The tenths of seconds register is reset to 0 when the clock start/stop bit (bit 2 of the control register) is set to logic 1. The units and tens of seconds are set up by the processor, giving time setting to the nearest second. All three registers can be read by the processor for time output.

Minutes Counters

There are two minutes counters:

- units of minutes
- tens of minutes

Both registers may be read to or written from as required.

Hours Counters

There are two hours counters:

- units of hours
- tens of hours

Both counters may be accessed for read or write operations as desired.

The tens of hours register has only one active bit and the top three bits are set to logic 0. Data bit 1 of the clock setting register is the AM/PM indicator; logic 0 indicating AM, logic 1 for PM.

Bit 0 of the clock setting register must be written to 0 for correct 12 hour operation.

Days Counters

There are two days counters:

- units of days
- tens of days

The days counters will count up to 28, 29, 30 or 31 depending on the state of the months counters and the leap year counter. The microprocessor has full read/write access to these registers.

Months Counters

There are two months counters:

- units of months
- tens of months

Both these counters have full read/write access.

Years Counters

There are two years counters:

- units of years
- tens of years

Both these counters have full read/write access. The years will count up to 99 and roll over to 00.

TABLE I. Address Decoding of Real-Time Clock Internal Registers

Register Selected	Address (Binary)				(Hex)	Access

12 Units Years	1	1	0	0	C	R/W
13 Tens Years	1	1	0	1	D	R/W
14 Day of Week	1	1	1	0	E	R/W
15 Clock Setting/ Interrupt Registers	1	1	1	1	F	R/W

There are three registers which control different operations of the clock:

- the clock setting register
- the interrupt register
- the control register.

The clock setting and interrupt registers both reside at address 15, access to one or the other being controlled by the interrupt select bit; data bit 1 of the control register.

The clock setting register programs the timekeeping of the clock. The 12-hour mode and the AM/PM indicator occupy bits 0 and 1, respectively. Data bits 2 and 3 set the leap year counter.

The interrupt register controls the operation of the interrupt timer, selecting the required delay period and either single or repeated interrupt.

The control register is responsible for controlling the operations of the clock and supplying status information to the processor. It appears as two different registers; one with write only access and one with read only access.

The write only register consists of a bank of four latches which control the internal processes of the clock.

The read only register contains two output data latches which will supply status information for the processor. Table III shows the mapping of the various control latches and status flags in the control register. The control register is located at address 0.

The write only portion of the control register contains four latches:

A logic 1 written into the test bit puts the device into test mode. This allows setting of the oscillator frequency as well as rapid testing of the device registers, if required. A more complete description is given in the Test Mode section. For normal operation the test bit is loaded with logic 0.

The clock start/stop bit stops the timekeeping of the clock and resets to 0 the tenths of seconds counter. The time of day may then be written into the various clock registers and the clock restarted synchronously with an external time source. Timekeeping is maintained thereafter.

A logic 1 written to the start/stop bit halts clock timing. Timing is restarted when the start/stop bit is written with a logic 0.

The interrupt select bit determines which of the two registers mapped onto address 15 will be accessed when this address is selected.

register. When the processor selects the interrupt register.

The interrupt start/stop bit controls the running of the interrupt timer. It is programmed in the same way as the clock start/stop bit; logic 1 to halt the interrupt and reset the timer, logic 0 to start interrupt timing.

When no interrupt is programmed (interrupt control register set to 0), the interrupt start/stop bit is automatically set to a logic 1. When any new interrupt is subsequently programmed, timing will not commence until the start/stop bit is loaded with 0.

In the single interrupt mode, interrupt timing stops when a timeout occurs. The processor restarts timing by writing logic 0 into the start/stop bit.

In repeated interrupt mode the interrupt timer continues to count with no intervention by the processor necessary.

Interrupt timing may be stopped in either mode by writing a logic 1 into the interrupt start/stop bit. The timer is reset and can be restarted in the normal way, giving a full time delay period before the next interrupt.

In general, the control register is set up such that writing 0's into it will start anything that is stopped, pull the clock out of test mode and select the clock setting register onto the bus. In other words, writing 0 will maintain normal clock operation and restart interrupt timing, etc.

The read only portion of the control register has two status outputs:

Since the MM58274C-12 keeps real time, the time data changes asynchronously with the processor and this may occur while the processor is reading time data out of the clock.

Some method of warning the processor when the time data has changed must thus be included. This is provided for by the data-changed flag located in bit 3 of the control register. This flag is set by the clock setting pulse which also clocks the time registers. Testing this bit can tell the processor whether or not the time has changed. The flag is cleared by a read of the control register but not by any write operations. No other register read has any effect on the state of the data-changed flag.

Data bit 0 is the interrupt flag. This flag is set whenever the interrupt timer times out, pulling the interrupt output low. In a polled interrupt routine the processor can test this flag to determine if the MM58274C-12 was the interrupting device. This interrupt flag and the interrupt output are both cleared by a read of the control register.

TABLE III. The Control Register Layout

Access (addr0)	DB3	DB2	DB1	DB0
Read From:	Data-Changed Flag	0	0	Interrupt Flag
Write To:	Test 0 = Normal 1 = Test Mode	Clock Start/Stop 0 = Clock Run 1 = Clock Stop	Interrupt Select 0 = Clock Setting Register 1 = Interrupt Register	Interrupt Start/Stop 0 = Interrupt Run 1 = Interrupt Stop

Functional Description (Continued)

Both of the flags and the interrupt output are reset by the trailing edge of the read strobe. The flag information is held latched during a control register read, guaranteeing that stable status information will always be read out by the processor.

Interrupt timeout is detected and stored internally if it occurs during a read of the control register, the interrupt output will then go low only after the read has been completed.

A clock setting pulse occurring during a control register read will *not* affect the data-changed flag since time data read out before or after the control read will not be affected by the time change.

METHODS OF DEVICE OPERATION

Test Mode

National Semiconductor uses test mode for functionally testing the MM58274C-12 after fabrication and again after packaging. Test mode can also be used to set up the oscillator frequency when the part is first commissioned.

Figure 4 shows the internal clock connections when the device is written into test mode. The 32.768 kHz oscillator is gated onto the interrupt output to provide a buffered output for initial frequency setting. This signal is driven from a TRI-STATE output buffer, enabling easy oscillator setting in systems where interrupt is not normally used and there is no external resistor on the pin.

If an interrupt is programmed, the 32.768 kHz output is switched off to allow high speed testing of the interrupt timer. The interrupt output will then function as normal.

The clock start/stop bit can be used to control the fast clocking of the time registers as shown in Figure 4.

Initialization

When it is first installed and power is applied, the device will need to be properly initialized. The following operation steps are recommended when the device is set up (all numbers are decimal):

1) Disable interrupt on the processor to allow oscillator setting. Write 15₁₀ into the control register: *The clock and interrupt start/stop bits are set to 1, ensuring that the clock and interrupt timers are both halted. Test mode and the interrupt register are selected.*

2) Write 0 to the interrupt register: *Ensure that there are no interrupts programmed and that the oscillator will be gated onto the interrupt output.*

3) Set oscillator frequency: *All timing has been halted and the oscillator is buffered out onto the interrupt line.*

4) Write 5 to the control register: *The clock is now out of test mode but is still halted. The clock setting register is now selected by the interrupt select bit.*

5) Write 0001 to all registers. This ensures starting with a valid BCD value in each register.

6) Set 12-hour mode: *Write 0 to data bit 0 of the clock setting register.*

7) Load Real-Time Registers: *All time registers (including Leap Years and AM/PM bit) may now be loaded in any order. Note that when writing to the clock setting register to set up Leap Years and AM/PM, the Hours Mode bit must not be altered from the value programmed in step 5.*

8) Write 0 to the control register: *This operation finishes the clock initialization by starting the time. The final control register write should be synchronized with an external time source.*

In general, timekeeping should be halted before the time data is altered in the clock. The data can, however, be altered at any time if so desired. Such may be the case if the user wishes to keep the clock corrected without having to stop and restart it; i.e., winter/summer time changing can be accomplished without halting the clock. This can be done in software by sensing the state of the data-changed flag and only altering time data just after the time has rolled over (data-changed flag set).

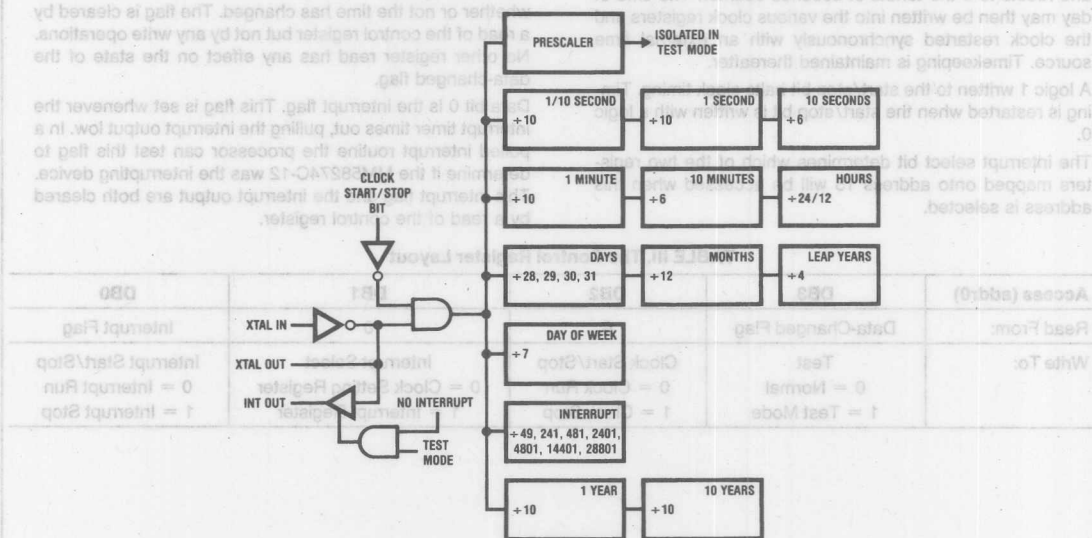

FIGURE 4. Test Mode Organization

TL/F/5602-6

Functional Description (Continued)

Reading the Time Registers

Using the data-changed flag technique supports microprocessors with block move facilities, as all the necessary time data may be read sequentially and then tested for validity as shown below.

- 1) Read the control register, address 0: *This is a dummy read to reset the data-changed flag (DCF) prior to reading the time registers.*
- 2) Read time registers: *All desired time registers are read out in a block.*
- 3) Read the control register and test DCF: *If DCF is cleared (logic 0), then no clock setting pulses have after occurred since step 1. All time data is guaranteed good and time reading is complete.*

If DCF is set (logic 1), then a time change has occurred since step 1 and time data may not be consistent. Repeat steps 2 and 3 until DCF is clear. The control read of step 3 will have reset DCF, automatically repeating the step 1 action.

Interrupt Programming

The interrupt timer generates interrupts at time intervals which are programmed into the interrupt register. A single interrupt after delay or repeated interrupts may be programmed. Table IIB lists the different time delays and the data words that select them in the interrupt register.

Once the interrupt register has been used to set up the delay time and to select for single or repeat, it takes no further part in the workings of the interrupt system. All activity by the processor then takes place in the control register.

Initializing:

- 1) Write 3 to the control register (AD0): *Clock timing continues, interrupt register selected and interrupt timing stopped.*
- 2) Write interrupt control word to address 15: *The interrupt register is loaded with the correct word (chosen from Table IIB) for the time delay required and for single or repeated interrupts.*
- 3) Write 0 or 2 to the control register: *Interrupt timing commences. Writing 0 selects the clock setting register onto the data bus; writing 2 leaves the interrupt register selected. Normal timekeeping remains unaffected.*

On Interrupt:

Read the control register and test for Interrupt Flag (bit 0).

If the flag is cleared (logic 0), then the device is not the source of the interrupt.

If the flag is set (logic 1), then the clock did generate an interrupt. The flag is reset and the interrupt output is cleared by the control register read that was used to test for interrupt.

Single Interrupt Mode:

When appropriate, write 0 or 2 to the control register to restart the interrupt timer.

Repeated Interrupt Mode:

Timing continues, synchronized with the control register write which originally started interrupt timing. No further intervention is necessary from the processor to maintain timing.

In either mode interrupt timing can be stopped by writing 1 into the control register (interrupt start/stop set to 1). Timing for the full delay period recommences when the interrupt start/stop bit is again loaded with 0 as normal.

IMPORTANT NOTE: Using the interrupt timer places a constraint on the maximum Read Strobe width which may be applied to the clock. Normally all registers may be read from with a t_{RW} down to DC (i.e., \overline{CS} and \overline{RD} held continuously low). When the interrupt timer is active however, the maximum read strobe width that can be applied to the control register (Addr 0) is 30 ms.

This restriction is to allow the interrupt timer to properly reset when it times out. Note that it only affects reading of the control register—all other addresses in the clock may be accessed with DC read strobes, regardless of the state of the interrupt timer. Writes to any address are unaffected.

NOTES ON AC TIMING REQUIREMENTS

Although the Switching Time Waveforms show Microbus control signals used for clock access, this does not preclude the use of the MM58274C-12 in other non-Microbus systems. Figure 5 is a simplified logic diagram showing how the control signals are gated internally to control access to the clock registers. From this diagram it is clear that \overline{CS} could be used to generate the internal data transfer strobes, with \overline{RD} and \overline{WR} inputs set up first. This situation is illustrated in Figure 6.

The internal data busses of the MM58274C-12 are fully CMOS, contributing to the flexibility of the control inputs. When determining the suitability of any given control signal pattern for the MM58274C-12 the timing specifications in AC Switching Characteristics should be examined. As long as these timings are met (or exceeded) the MM58274C-12 will function correctly.

When the MM58274C-12 is connected to the system via a peripheral port, the freedom from timing constraints allows for very simple control signal generation, as in Figure 7. For reading (Figure 7a), Address, \overline{CS} and \overline{RD} may be activated simultaneously and the data will be available at the port after t_{AD-max} (650 ns). For writing (Figure 7b), the address and data may be applied simultaneously; 70 ns later \overline{CS} and \overline{WR} may be strobed together.

Functional Description (Continued)

(2) Read control register ADO. This is a dummy read to reset the interrupt timer. (3) Read control register ADO until the data-changed flag is set. (4) While 0 or 2 to control register interrupt timing command.

Time Reading with Very Slow Rate Cycles
The interrupt timer is then 100 ms to complete reading of all the necessary time registers (e.g., when CMOS processors are used) or when high-level interpreted languages (e.g., BASIC) are used, then the data-changed flag will always be set when tested and is of no value. In this case, the time registers themselves must be tested to ensure data accuracy.

The technique below will detect both time changing between codes (i.e., between tens of minutes, hours, and days) and also changing during read, which can produce invalid data.

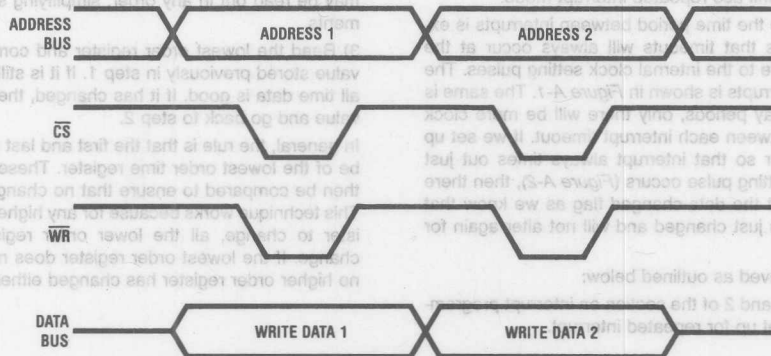

(2) Read out all the time registers required. The registers may be read out in any order, simplifying software requirements.

(3) Read the lowest order time register and compare it with the value stored previously in step 1. If it is still the same, then all time data is good. If it has changed, then store the new value and go back to step 2.

Interpretation: The rule is that the first and last reads must both be to the lowest order time register. These two values can then be compared to ensure that no change has occurred. This technique works because for any higher order time register to change, all the lower order registers must also change. If the lowest order register does not change, then no higher order register has changed either.

Functional Description (Continued)

Time Reading Using Interrupts
In systems such as point-to-point terminals and data registers, time reading is usually only required on a random demand basis. Using the interrupt timer for this type of system is ideal for this type of system.

Some systems, however, need to know the time of day, time, e.g., industrial timers/process controllers, TV/VCR clocks, any system where real time is displayed. The interrupt timer on the MM58274C-12 can generate interrupts synchronously with the time registers changing, using software to provide the initial synchronization.

In single interrupt mode the processor is responsible for initiating each timing cycle and for the interrupt timer.

The interrupt timer mode the period from the first process start to the first timeout is also a delay period. The following interrupt maintain accurate delay periods relative to the first timeout. Thus, to utilize interrupt to control time reading, we will use repeated interrupt mode.

In repeated mode the time between successive interrupts is a constant, which means that the interrupt timer will always occur at the same point relative to the internal clock setting pulses. The case for 0.1s intervals is shown in Figure A-1. The same is true for other delay periods, only time will be more clock setting pulses between each interrupt timeout. We set up the interrupt timer so that interrupt always comes out just after the clock setting pulse occurs (Figure A-2), then there is no need to wait for the interrupt flag as we know that the time data has just changed and will not change again for another 100 ms.

This can be achieved as outlined below:

(1) Follow steps 1 and 2 of the simple port generated interrupt in step 2 set up for repeated interrupt mode.

Functional Description (Continued)

APPLICATION HINTS

Time Reading Using Interrupt

In systems such as point of sale terminals and data loggers, time reading is usually only required on a random demand basis. Using the data-changed flag as outlined in the section on methods of operation is ideal for this type of system. Some systems, however, need to sense a change in real time; e.g., industrial timers/process controllers, TV/VCR clocks, any system where real time is displayed.

The interrupt timer on the MM58274C-12 can generate interrupts synchronously with the time registers changing, using software to provide the initial synchronization.

In single interrupt mode the processor is responsible for initiating each timing cycle and the timed period is accurate to ± 1 ms.

In repeated interrupt mode the period from the initial processor start to the first timeout is also only accurate to ± 1 ms. The following interrupts maintain accurate delay periods relative to the first timeout. Thus, to utilize interrupt to control time reading, we will use repeated interrupt mode.

In repeated mode the time period between interrupts is exact, which means that timeouts will always occur at the same point relative to the internal clock setting pulses. The case for 0.1s interrupts is shown in *Figure A-1*. The same is true for other delay periods, only there will be more clock setting pulses between each interrupt timeout. If we set up the interrupt timer so that interrupt always times out just after the clock setting pulse occurs (*Figure A-2*), then there is no need to test the data-changed flag as we know that the time data has just changed and will not alter again for another 100 ms.

This can be achieved as outlined below:

- 1) Follow steps 1 and 2 of the section on interrupt programming. In step 2 set up for repeated interrupt.

2) Read control register AD0: *This is a dummy read to reset the data-changed flag.*

3) Read control register AD0 until data-changed flag is set.

4) Write 0 or 2 to control register. Interrupt timing commences.

Time Reading with Very Slow Read Cycles

If a system takes longer than 100 ms to complete reading of all the necessary time registers (e.g., when CMOS processors are used) or where high level interpreted language routines are used, then the data-changed flag will always be set when tested and is of no value. In this case, the time registers themselves must be tested to ensure data accuracy.

The technique below will detect both time changing *between* read strobes (i.e., between reading tens of minutes and units of hours) and also time changing *during* read, which can produce invalid data.

1) Read and store the value of the *lowest* order time register required.

2) Read out all the time registers required. The registers may be read out in any order, simplifying software requirements.

3) Read the lowest order register and compare it with the value stored previously in step 1. If it is still the same, then all time data is good. If it has changed, then store the new value and go back to step 2.

In general, the rule is that the first and last reads *must* both be of the lowest order time register. These two values can then be compared to ensure that no change has occurred. This technique works because for any higher order time register to change, all the lower order registers must also change. If the lowest order register does not change, then no higher order register has changed either.

WRITE TIMING: DATA FROM MICROPROCESSOR TO PERIPHERAL $V_{DD} = 5V \pm 0.5V$

Symbol	Parameter	Commercial Specification			Units
		T _A = −40°C to +85°C			
		Min	Typ	Max	
t _{AW}	Address Bus Valid to Write Strobe  (Note 4, Note 6)	400	125		ns
t _{CSW}	Chip Select On to Write Strobe 	250	100		ns
t _{DW}	Data Bus Valid to Write Strobe 	400	220		ns
t _{WW}	Write Strobe Width (Note 6)	250	95		ns
t _{WCS}	Chip Select Hold Time Following Write Strobe 	0			ns
t _{WA}	Address Bus Hold Time Following Write Strobe 	0			ns
t _{WD}	Data Bus Hold Time Following Write Strobe 	100	35		ns
t _{AWS}	Address Bus Valid Before Start of Write Strobe	70	20		ns

Note 3: Except for special case restriction: with interrupts programmed, max read strobe width of control register (ADDR 0) is 30 ms. See section on Interrupt Programming.

Note 4: All timings measured to the trailing edge of write strobe (data latched by the trailing edge of \overline{WR}).

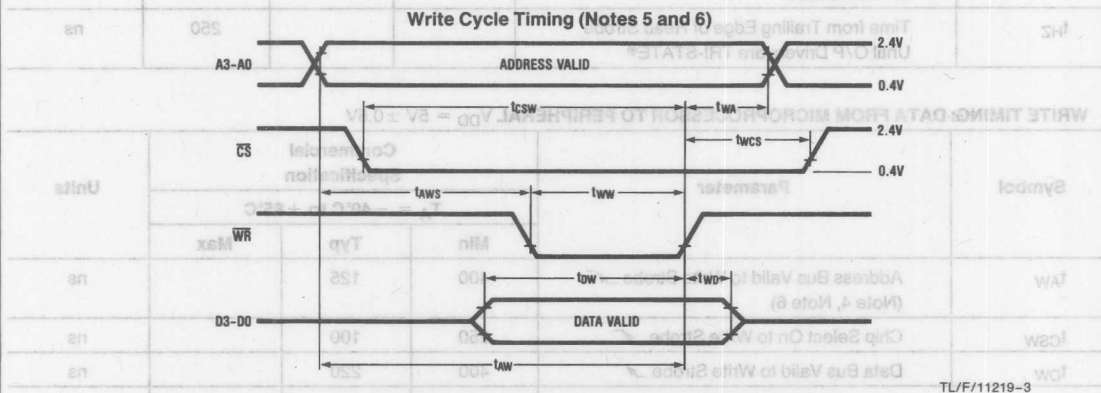

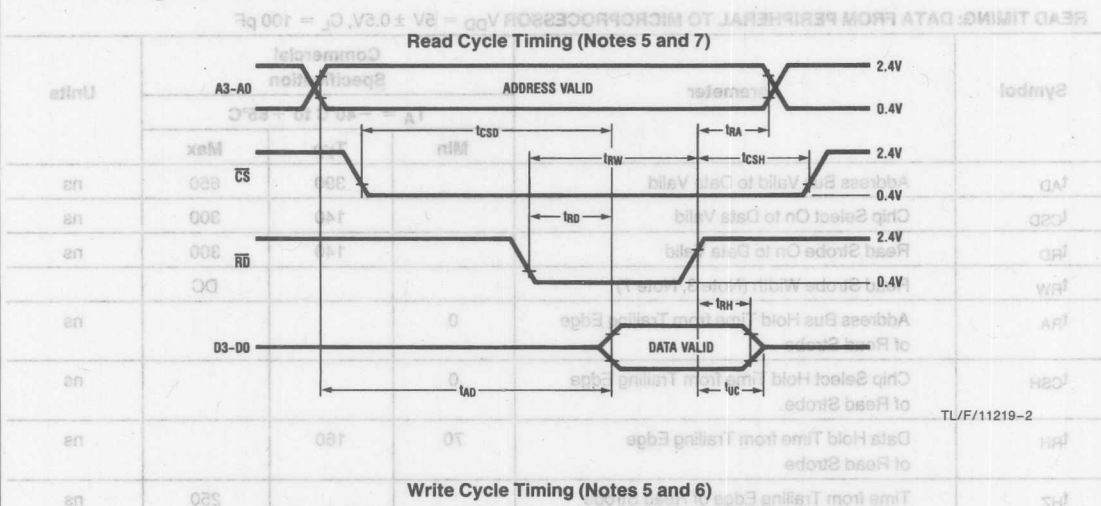

Note 5: Input test waveform peak voltages are 2.4V and 0.4V. Output signals are measured to their 2.4V and 0.4V levels.

Note 6: Write strobe as used in the Write Timing Table is defined as the period when both chip select and write inputs are low, ie., $\overline{WS} = \overline{CS} + \overline{WR}$. Hence write strobe commences when both signals are low, and terminates when the first signal returns high.

Note 7: Read strobe as used in the Read Timing Table is defined as the period when both chip select and read inputs are low, ie., $\overline{RS} = \overline{CS} + \overline{RD}$.

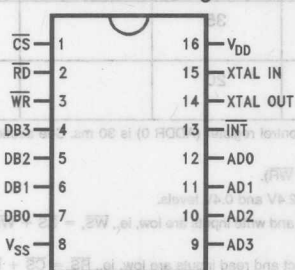

Note 8: Typical numbers are at $V_{CC} = 5.0V$ and $T_A = 25^\circ\text{C}$.

ing extended timekeeping up to units and tens of years. To enhance the device further, a number of other features have been added including: 12 or 24 hours counting, a testable data-changed flag giving easy error-free time reading and simplified interrupt control.

A buffered oscillator signal appears on the interrupt output when the device is in test mode. This allows for easy oscillator setting when the device is initially powered up in a system.

The counters are arranged as 4-bit words and can be randomly accessed for time reading and setting. The counters output in BCD (binary coded decimal) 4-bit numbers. Any register which has less than 4 bits (e.g., days of week uses only 3 bits) will return a logic 0 on any unused bits. When written to, the unused inputs will be ignored.

Writing a logic 1 to the clock start/stop control bit resets the internal oscillator divider chain and the tenths of seconds counter. Writing a logic 0 will start the clock timing from the nearest second. The time then updates every 100 ms with all counters changing synchronously. Time changing during a read is detected by testing the data-changed bit of the control register after completing a string of clock register reads.

Interrupt delay times of 0.1s, 0.5s, 1s, 5s, 10s, 30s or 60s can be selected with single or repeated interrupt outputs. The open drain output is pulled low whenever the interrupt timer times out and is cleared by reading the control register.

of the chip. The 16-pin package outline is shown in Figure 2.

Crystal Oscillator

This consists of a CMOS inverter/amplifier with an on-chip bias resistor. Externally a 20 pF capacitor, a 6 pF–36 pF trimmer capacitor and a crystal are suggested to complete the 32.768 kHz timekeeping oscillator circuit.

The 6 pF–36 pF trimmer fine tunes the crystal load impedance, optimizing the oscillator stability. When properly adjusted (i.e., to the crystal frequency of 32.768 kHz), the circuit will display a frequency variation with voltage of less than 3 ppm/V. When an external oscillator is used, connect to oscillator input and float (no connection) the oscillator output.

When the chip is enabled into test mode, the oscillator is gated onto the interrupt output pin giving a buffered oscillator output that can be used to set the crystal frequency when the device is installed in a system. For further information see the section on Test Mode.

Divider Chain

The crystal oscillator is divided down in three stages to produce a 10 Hz frequency setting pulse. The first stage is a non-integer divider which reduces the 32.768 kHz input to 30.720 kHz. This is further divided by a 9-stage binary ripple counter giving an output frequency of 60 Hz. A 3-stage Johnson counter divides this by six, generating a 10 Hz output. The 10 Hz clock is gated with the 32.768 kHz crystal frequency to provide clock setting pulses of 15.26 μ s duration. The setting pulse drives all the time registers on the

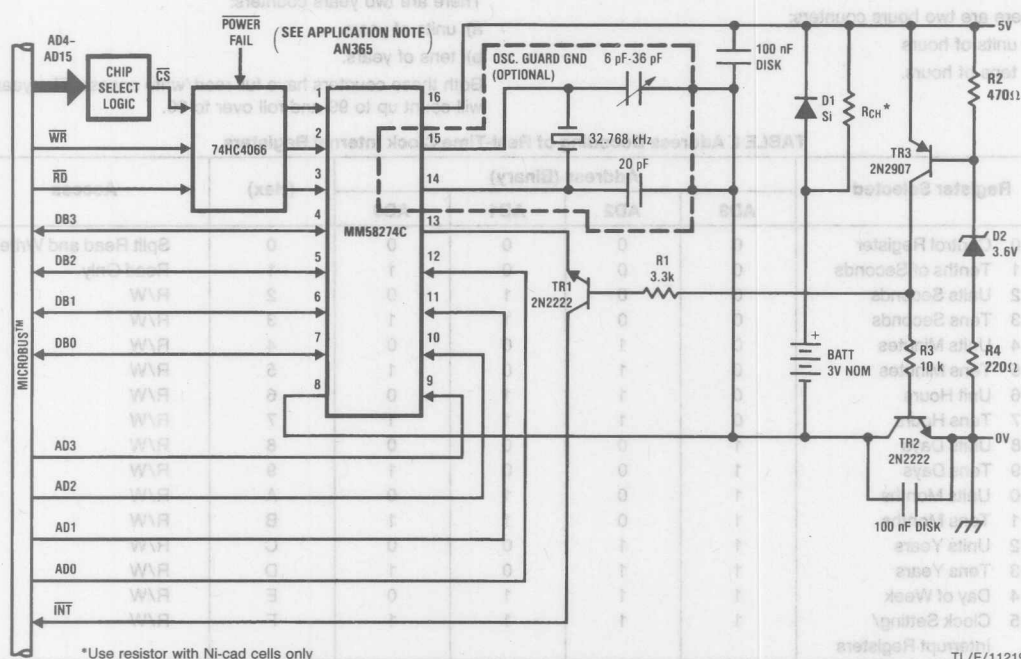

FIGURE 3. Typical System Connection Diagram

TL/F/11219-6

Functional Description (Continued)

device which are synchronously clocked by this signal. All time data and data-changed flag change on the falling edge of the clock setting pulse.

Data-Changed Flag

The data-changed flag is set by the clock setting pulse to indicate that the time data has been altered since the clock was last read. This flag occupies bit 3 of the control register where it can be tested by the processor to sense data-changed. It will be reset by a read of the control register. See the section, "Methods of Device Operation", for suggested clock reading techniques using this flag.

Seconds Counters

There are three counters for seconds:

- tenths of seconds
- units of seconds
- tens of seconds

The registers are accessed at the addresses shown in Table I. The tenths of seconds register is reset to 0 when the clock start/stop bit (bit 2 of the control register) is set to logic 1. The units and tens of seconds are set up by the processor, giving time setting to the nearest second. All three registers can be read by the processor for time output.

Minutes Counters

There are two minutes counters:

- units of minutes
- tens of minutes

Both registers may be read to or written from as required.

Hours Counters

There are two hours counters:

- units of hours
- tens of hours

Both counters may be accessed for read or write operations as desired.

In 12-hour mode, the tens of hours register has only one active bit and the top three bits are set to logic 0. Data bit 1 of the clock setting register is the AM/PM indicator; logic 0 indicating AM, logic 1 for PM.

When 24-hour mode is programmed, the tens of hours register reads out two bits of data and the two most significant bits are set to logic 0. There is no AM/PM indication and bit 1 of the clock setting register will read out a logic 0.

In both 12/24-hour modes, the units of hours will read out four active data bits. 12 or 24-hour mode is selected by bit 0 of the clock setting register, logic 0 for 12-hour mode, logic 1 for the 24-hour mode.

Days Counters

There are two days counters:

- units of days
- tens of days

The days counters will count up to 28, 29, 30 or 31 depending on the state of the months counters and the leap year counter. The microprocessor has full read/write access to these registers.

Months Counters

There are two months counters:

- units of months
- tens of months

Both these counters have full read/write access.

Years Counters

There are two years counters:

- units of years
- tens of years

Both these counters have full read/write access. The years will count up to 99 and roll over to 00.

TABLE I. Address Decoding of Real-Time Clock Internal Registers

Register Selected	Address (Binary)				(Hex)	Access
	AD3	AD2	AD1	AD0		
0 Control Register	0	0	0	0	0	Split Read and Write
1 Tenths of Seconds	0	0	0	1	1	Read Only
2 Units Seconds	0	0	1	0	2	R/W
3 Tens Seconds	0	0	1	1	3	R/W
4 Units Minutes	0	1	0	0	4	R/W
5 Tens Minutes	0	1	0	1	5	R/W
6 Unit Hours	0	1	1	0	6	R/W
7 Tens Hours	0	1	1	1	7	R/W
8 Units Days	1	0	0	0	8	R/W
9 Tens Days	1	0	0	1	9	R/W
10 Units Months	1	0	1	0	A	R/W
11 Tens Months	1	0	1	1	B	R/W
12 Units Years	1	1	0	0	C	R/W
13 Tens Years	1	1	0	1	D	R/W
14 Day of Week	1	1	1	0	E	R/W
15 Clock Setting/ Interrupt Registers	1	1	1	1	F	R/W

Functional Description (Continued)

Day of Week Counter

The day of week counter increments as the time rolls from 23:59 to 00:00 (11:59 PM to 12:00 AM in 12-hour mode). It counts from 1 to 7 and rolls back to 1. Any day of the week may be specified as day 1.

Clock Setting Register/Interrupt Register

The interrupt select bit in the control register determines which of these two registers is accessible to the processor at address 15. Normal clock and interrupt timing operations will always continue regardless of which register is selected onto the bus. The layout of these registers is shown in Table II.

The clock setting register is comprised of three separate functions:

- leap year counter: bits 2 and 3
- AM/PM indicator: bit 1
- 12-hour mode set: bit 0 (see Table IIA).

The leap year counter is a 2-stage binary counter which is clocked by the months counter. It changes state as the time rolls over from 11:59 on December 31 to 00:00 on January 1.

The counter should be loaded with the 'number of years since last leap year' e.g., if 1980 was the last leap year, a clock programmed in 1983 should have 3 stored in the leap year counter. If the clock is programmed during a leap year, then the leap year counter should be set to 0. The contents of the leap year counter can be read by the μ P.

The AM/PM indicator returns a logic 0 for AM and a logic 1 for PM. It is clocked when the hours counter rolls from 11:59 to 12:00 in 12-hour mode. In 24-hour mode this bit is set to logic 0.

The 12/24-hour mode set determines whether the hours counter counts from 1 to 12 or from 0 to 23. It also controls the AM/PM indicator, enabling it for 12-hour mode and forcing it to logic 0 for the 24-hour mode. The 12/24-hour mode bit is set to logic 0 for 12-hour mode and it is set to logic 1 for 24-hour mode.

IMPORTANT NOTE: Hours mode and AM/PM bits cannot be set in the same write operation. See the section on Initialization (Methods of Device Operation) for a suggested setting routine.

All bits in the clock setting register may be read by the processor.

The interrupt register controls the operation of the timer for interrupt output. The processor programs this register for single or repeated interrupts at the selected time intervals.

The lower three bits of this register set the time delay period that will occur between interrupts. The time delays that can be programmed and the data words that select these are outlined in Table IIB.

Data bit 3 of the interrupt register sets for either single or repeated interrupts; logic 0 gives single mode, logic 1 sets for repeated mode.

Using the interrupt is described in the Device Operation section.

TABLE IIA. Clock Setting Register Layout

Function	Data Bits Used				Comments	Access
	DB3	DB2	DB1	DB0		
Leap Year Counter	X	X			0 Indicates a Leap Year	R/W
AM/PM Indicator (12-Hour Mode)			X		0 = AM 1 = PM	R/W
12/24-Hour Select Bit				X	0 in 24-Hour Mode 0 = 12-Hour Mode 1 = 24-Hour Mode	R/W

TABLE IIB. Interrupt Control Register

Function	Comments	Control Word			
		DB3	DB2	DB1	DB0
No Interrupt	Interrupt output cleared, start/stop bit set to 1.	X	0	0	0
0.1 Second		0/1	0	0	1
0.5 Second		0/1	0	1	0
1 Second		0/1	0	1	1
5 Seconds	DB3 = 0 for single interrupt	0/1	1	0	0
10 Seconds	DB3 = 1 for repeated interrupt	0/1	1	0	1
30 Seconds		0/1	1	1	0
60 Seconds		0/1	1	1	1

Timing Accuracy: single interrupt mode (all time delays): ± 1 ms

Repeated Mode: ± 1 ms on initial timeout, thereafter synchronous with first interrupt (i.e., timing errors do not accumulate).

Functional Description (Continued)

Control Register

There are three registers which control different operations of the clock:

- a) the clock setting register
- b) the interrupt register
- c) the control register.

The clock setting and interrupt registers both reside at address 15, access to one or the other being controlled by the interrupt select bit; data bit 1 of the control register.

The clock setting register programs the timekeeping of the clock. The 12/24-hour mode select and the AM/PM indicator for 12-hour mode occupy bits 0 and 1, respectively. Data bits 2 and 3 set the leap year counter.

The interrupt register controls the operation of the interrupt timer, selecting the required delay period and either single or repeated interrupt.

The control register is responsible for controlling the operations of the clock and supplying status information to the processor. It appears as two different registers; one with write only access and one with read only access.

The write only register consists of a bank of four latches which control the internal processes of the clock.

The read only register contains two output data latches which will supply status information for the processor. Table III shows the mapping of the various control latches and status flags in the control register. The control register is located at address 0.

The write only portion of the control register contains four latches:

A logic 1 written into the test bit puts the device into test mode. This allows setting of the oscillator frequency as well as rapid testing of the device registers, if required. A more complete description is given in the Test Mode section. For normal operation the test bit is loaded with logic 0.

The clock start/stop bit stops the timekeeping of the clock and resets to 0 the tenths of seconds counter. The time of day may then be written into the various clock registers and the clock restarted synchronously with an external time source. Timekeeping is maintained thereafter.

A logic 1 written to the start/stop bit halts clock timing. Timing is restarted when the start/stop bit is written with a logic 0.

The interrupt select bit determines which of the two registers mapped onto address 15 will be accessed when this address is selected.

A logic 0 in the interrupt select bit makes the clock setting register available to the processor. A logic 1 selects the interrupt register.

The interrupt start/stop bit controls the running of the interrupt timer. It is programmed in the same way as the clock start/stop bit; logic 1 to halt the interrupt and reset the timer, logic 0 to start interrupt timing.

When no interrupt is programmed (interrupt control register set to 0), the interrupt start/stop bit is automatically set to a logic 1. When any new interrupt is subsequently programmed, timing will not commence until the start/stop bit is loaded with 0.

In the single interrupt mode, interrupt timing stops when a timeout occurs. The processor restarts timing by writing logic 0 into the start/stop bit.

In repeated interrupt mode the interrupt timer continues to count with no intervention by the processor necessary.

Interrupt timing may be stopped in either mode by writing a logic 1 into the interrupt start/stop bit. The timer is reset and can be restarted in the normal way, giving a full time delay period before the next interrupt.

In general, the control register is set up such that writing 0's into it will start anything that is stopped, pull the clock out of test mode and select the clock setting register onto the bus. In other words, writing 0 will maintain normal clock operation and restart interrupt timing, etc.

The read only portion of the control register has two status outputs:

Since the MM58274C keeps real time, the time data changes asynchronously with the processor and this may occur while the processor is reading time data out of the clock.

Some method of warning the processor when the time data has changed must thus be included. This is provided for by the data-changed flag located in bit 3 of the control register. This flag is set by the clock setting pulse which also clocks the time registers. Testing this bit can tell the processor whether or not the time has changed. The flag is cleared by a read of the control register but not by any write operations. No other register read has any effect on the state of the data-changed flag.

Data bit 0 is the interrupt flag. This flag is set whenever the interrupt timer times out, pulling the interrupt output low. In a polled interrupt routine the processor can test this flag to determine if the MM58274C was the interrupting device. This interrupt flag and the interrupt output are both cleared by a read of the control register.

TABLE III. The Control Register Layout

Access (addr0)	DB3	DB2	DB1	DB0
Read From:	Data-Changed Flag	0	0	Interrupt Flag
Write To:	Test 0 = Normal 1 = Test Mode	Clock Start/Stop 0 = Clock Run 1 = Clock Stop	Interrupt Select 0 = Clock Setting Register 1 = Interrupt Register	Interrupt Start/Stop 0 = Interrupt Run 1 = Interrupt Stop

Functional Description (Continued)

Both of the flags and the interrupt output are reset by the trailing edge of the read strobe. The flag information is held latched during a control register read, guaranteeing that stable status information will always be read out by the processor.

Interrupt timeout is detected and stored internally if it occurs during a read of the control register, the interrupt output will then go low only after the read has been completed.

A clock setting pulse occurring during a control register read will not affect the data-changed flag since time data read out before or after the control read will not be affected by the time change.

METHODS OF DEVICE OPERATION

Test Mode

National Semiconductor uses test mode for functionally testing the MM58274C after fabrication and again after packaging. Test mode can also be used to set up the oscillator frequency when the part is first commissioned.

Figure 4 shows the internal clock connections when the device is written into test mode. The 32.768 kHz oscillator is gated onto the interrupt output to provide a buffered output for initial frequency setting. This signal is driven from a TRI-STATE output buffer, enabling easy oscillator setting in systems where interrupt is not normally used and there is no external resistor on the pin.

If an interrupt is programmed, the 32.768 kHz output is switched off to allow high speed testing of the interrupt timer. The interrupt output will then function as normal.

The clock start/stop bit can be used to control the fast clocking of the time registers as shown in Figure 4.

Initialization

When it is first installed and power is applied, the device will need to be properly initialized. The following operation steps are recommended when the device is set up (all numbers are decimal):

- 1) Disable interrupt on the processor to allow oscillator setting. Write 15₁₀ into the control register: *The clock and interrupt start/stop bits are set to 1, ensuring that the clock and interrupt timers are both halted. Test mode and the interrupt register are selected.*
- 2) Write 0 to the interrupt register: *Ensure that there are no interrupts programmed and that the oscillator will be gated onto the interrupt output.*
- 3) Set oscillator frequency: *All timing has been halted and the oscillator is buffered out onto the interrupt line.*
- 4) Write 5 to the control register: *The clock is now out of test mode but is still halted. The clock setting register is now selected by the interrupt select bit.*
- 5) Write 0001 to all registers. This ensures starting with a valid BCD value in each register.
- 6) Set 12/24 Hours Mode: *Write to the clock setting register to select the hours counting mode required.*
- 7) Load Real-Time Registers: *All time registers (including Leap Years and AM/PM bit) may now be loaded in any order. Note that when writing to the clock setting register to set up Leap Years and AM/PM, the Hours Mode bit must not be altered from the value programmed in step 5.*
- 8) Write 0 to the control register: *This operation finishes the clock initialization by starting the time. The final control register write should be synchronized with an external time source.*

In general, timekeeping should be halted before the time data is altered in the clock. The data can, however, be altered at any time if so desired. Such may be the case if the user wishes to keep the clock corrected without having to stop and restart it; i.e., winter/summer time changing can be accomplished without halting the clock. This can be done in software by sensing the state of the data-changed flag and only altering time data just after the time has rolled over (data-changed flag set).

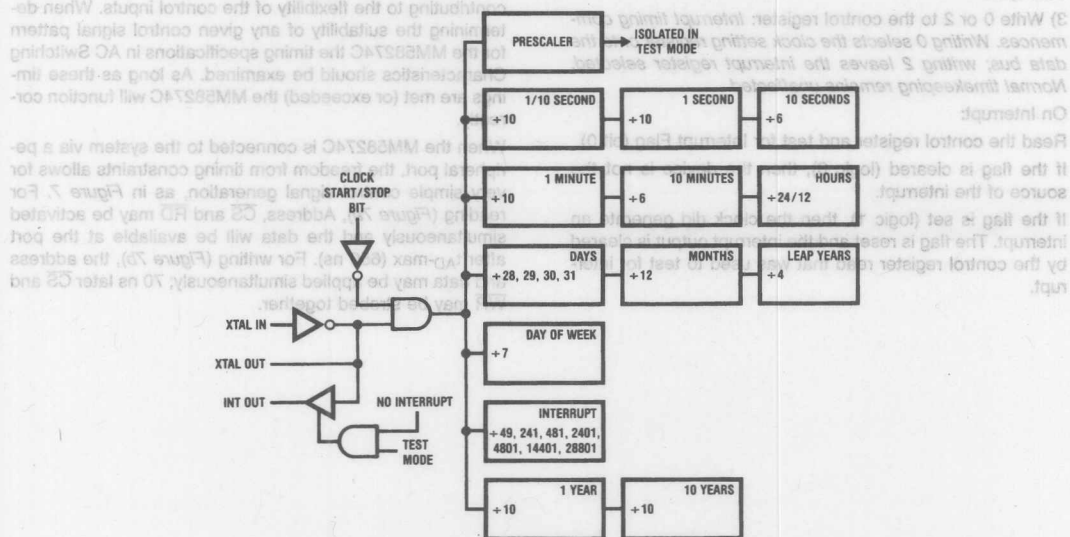

FIGURE 4. Test Mode Organization

TL/F/11219-7

Functional Description (Continued)

Reading the Time Registers

Using the data-changed flag technique supports microprocessors with block move facilities, as all the necessary time data may be read sequentially and then tested for validity as shown below.

- 1) Read the control register, address 0: *This is a dummy read to reset the data-changed flag (DCF) prior to reading the time registers.*
- 2) Read time registers: *All desired time registers are read out in a block.*
- 3) Read the control register and test DCF: *If DCF is cleared (logic 0), then no clock setting pulses have after occurred since step 1. All time data is guaranteed good and time reading is complete.*

If DCF is set (logic 1), then a time change has occurred since step 1 and time data may not be consistent. Repeat steps 2 and 3 until DCF is clear. The control read of step 3 will have reset DCF, automatically repeating the step 1 action.

Interrupt Programming

The interrupt timer generates interrupts at time intervals which are programmed into the interrupt register. A single interrupt after delay or repeated interrupts may be programmed. Table IIB lists the different time delays and the data words that select them in the interrupt register.

Once the interrupt register has been used to set up the delay time and to select for single or repeat, it takes no further part in the workings of the interrupt system. All activity by the processor then takes place in the control register.

Initializing:

- 1) Write 3 to the control register (AD0): *Clock timing continues, interrupt register selected and interrupt timing stopped.*
- 2) Write interrupt control word to address 15: *The interrupt register is loaded with the correct word (chosen from Table IIB) for the time delay required and for single or repeated interrupts.*
- 3) Write 0 or 2 to the control register: *Interrupt timing commences. Writing 0 selects the clock setting register onto the data bus; writing 2 leaves the interrupt register selected. Normal timekeeping remains unaffected.*

On Interrupt:

Read the control register and test for Interrupt Flag (bit 0). If the flag is cleared (logic 0), then the device is not the source of the interrupt.

If the flag is set (logic 1), then the clock did generate an interrupt. The flag is reset and the interrupt output is cleared by the control register read that was used to test for interrupt.

Single Interrupt Mode:

When appropriate, write 0 or 2 to the control register to restart the interrupt timer.

Repeated Interrupt Mode:

Timing continues, synchronized with the control register write which originally started interrupt timing. No further intervention is necessary from the processor to maintain timing.

In either mode interrupt timing can be stopped by writing 1 into the control register (interrupt start/stop set to 1). Timing for the full delay period recommences when the interrupt start/stop bit is again loaded with 0 as normal.

IMPORTANT NOTE: Using the interrupt timer places a constraint on the maximum Read Strobe width which may be applied to the clock. Normally all registers may be read from with a t_{PW} down to DC (i.e., \overline{CS} and \overline{RD} held continuously low). When the interrupt timer is active however, the maximum read strobe width that can be applied to the control register (Addr 0) is 30 ms.

This restriction is to allow the interrupt timer to properly reset when it times out. Note that it only affects reading of the control register—all other addresses in the clock may be accessed with DC read strobes, regardless of the state of the interrupt timer. Writes to any address are unaffected.

NOTES ON AC TIMING REQUIREMENTS

Although the Switching Time Waveforms show Microbus control signals used for clock access, this does not preclude the use of the MM58274C in other non-Microbus systems. Figure 5 is a simplified logic diagram showing how the control signals are gated internally to control access to the clock registers. From this diagram it is clear that \overline{CS} could be used to generate the internal data transfer strobes, with \overline{RD} and \overline{WR} inputs set up first. This situation is illustrated in Figure 6.

The internal data busses of the MM58274C are fully CMOS, contributing to the flexibility of the control inputs. When determining the suitability of any given control signal pattern for the MM58274C the timing specifications in AC Switching Characteristics should be examined. As long as these timings are met (or exceeded) the MM58274C will function correctly.

When the MM58274C is connected to the system via a peripheral port, the freedom from timing constraints allows for very simple control signal generation, as in Figure 7. For reading (Figure 7a), Address, \overline{CS} and \overline{RD} may be activated simultaneously and the data will be available at the port after t_{AD-max} (650 ns). For writing (Figure 7b), the address and data may be applied simultaneously; 70 ns later \overline{CS} and \overline{WR} may be strobed together.

FIGURE 7. Simple Port Generated Control Signals

Time Reading Using Interrupt

In systems such as point of sale terminals and data loggers, time reading is usually only required on a random demand basis. Using the data-changed flag as outlined in the section on methods of operation is ideal for this type of system. Some systems, however, need to sense a change in real time; e.g., industrial timers/process controllers, TV/VCR clocks, any system where real time is displayed.

The interrupt timer on the MM58274C can generate interrupts synchronously with the time registers changing, using software to provide the initial synchronization.

In single interrupt mode the processor is responsible for initiating each timing cycle and the timed period is accurate to ± 1 ms.

In repeated interrupt mode the period from the initial processor start to the first timeout is also only accurate to ± 1 ms. The following interrupts maintain accurate delay periods relative to the first timeout. Thus, to utilize interrupt to control time reading, we will use repeated interrupt mode.

In repeated mode the time period between interrupts is exact, which means that timeouts will always occur at the same point relative to the internal clock setting pulses. The case for 0.1s interrupts is shown in Figure A-1. The same is true for other delay periods, only there will be more clock setting pulses between each interrupt timeout. If we set up the interrupt timer so that interrupt always times out just after the clock setting pulse occurs (Figure A-2), then there is no need to test the data-changed flag as we know that the time data has just changed and will not alter again for another 100 ms.

This can be achieved as outlined below:

1) Follow steps 1 and 2 of the section on interrupt programming. In step 2 set up for repeated interrupt.

3) Read control register AD0 until data-changed flag is set.

4) Write 0 or 2 to control register. Interrupt timing commences.

Time Reading with Very Slow Read Cycles

If a system takes longer than 100 ms to complete reading of all the necessary time registers (e.g., when CMOS processors are used) or where high level interpreted language routines are used, then the data-changed flag will always be set when tested and is of no value. In this case, the time registers themselves must be tested to ensure data accuracy.

The technique below will detect both time changing *between* read strobes (i.e., between reading tens of minutes and units of hours) and also time changing *during* read, which can produce invalid data.

1) Read and store the value of the *lowest* order time register required.

2) Read out all the time registers required. The registers may be read out in any order, simplifying software requirements.

3) Read the lowest order register and compare it with the value stored previously in step 1. If it is still the same, then all time data is good. If it has changed, then store the new value and go back to step 2.

In general, the rule is that the first and last reads *must* both be of the lowest order time register. These two values can then be compared to ensure that no change has occurred. This technique works because for any higher order time register to change, all the lower order registers must also change. If the lowest order register does not change, then no higher order register has changed either.

MM58174A

Microprocessor-Compatible Real-Time Clock

General Description

The MM58174A is a low-threshold metal-gate CMOS circuit that functions as a real-time clock and calendar in bus-oriented microprocessor systems. The device includes an interrupt timer which may be programmed to one of three times. Timekeeping is maintained down to 2.2V to allow low power standby battery operation. The timebase is generated from a 32768 Hz crystal-controlled oscillator.

Features

- Microprocessor compatible
- Tenths of seconds, seconds, tens of seconds, minutes, tens of minutes, day of week, days, tens of days, months, tens of months, independent registers
- Automatic leap year calculation
- Internal pull-ups to safeguard data
- Protection for read during data changing
- Independent interrupt system with open drain output

Functional Description

The MM58174 is a microprocessor bus-oriented real-time clock. The circuit includes addressable real-time counters for tenths of seconds through months and a write only register for leap year calculation. The counters are arranged as bytes of four bits each. When addressed a byte will appear on the data I/O bus so that each word can be accessed independently. If any byte does not contain four bits (e.g., days of the week uses only 3 bits), the unused bits will be unrecognized during a write operation and tied to V_{SS} during a read operation.

The addressable reset latch causes the pre-scaler, tenths of seconds, seconds, and tens of seconds to be held in a reset condition. If a register is updated during a read operation the I/O data is prevented from updating and a subsequent read will return the illegal b.c.d. code '1111'. The interrupt timer may be programmed for intervals of 0.5 second, 5 seconds, or 60 seconds and may be coded as a single or repeated operation. The open drain interrupt output is pulled to V_{SS} when the timer times out and reading the interrupt register provides the internal selected information.

Circuit Description

The block diagram shown in Figure 1 shows the structure of the CMOS clock chip. A 16-pin DIL package is used.

CRYSTAL OSCILLATOR

This consists of a CMOS inverter/amplifier with on-chip bias resistor and capacitors. A single 6 pF–36 pF trimmer is all that is required to fine tune the crystal (see Figure 2). However, for improved stability, some crystals may require a capacitor of typical value 20 pF to be added between pin 14 and ground. The output of the oscillator is blocked by the start/stop F/F.

NON-INTEGGER DIVIDER

This counter divides the incoming 32,768 Hz frequency by 15/16 down to 30,720 Hz.

FIXED DIVIDER (512)

This is a standard 9-stage binary ripple counter. Output frequency is 60 Hz. This counter is reset to zero by start/stop F/F.

FIXED DIVIDER (6)

This is a 3-stage Johnson counter with a 10 Hz output signal. This counter is reset to zero state by the start/stop F/F.

SYNCHRONIZATION STAGE

Both 10 Hz and 32,768 Hz clocks are fed into this section. It is used to generate a pulse of 15.25 μ s width on the rising edge of each 10 Hz pulse.

This pulse is used to increment all the seconds, minutes, hours, days, months, and year counter and also to set the data changed F/F.

DATA CHANGED F/F

This is set by the rising edge of each 10 Hz pulse to indicate that the clock value has changed since the last read operation. It is reset by any clock read command.

The flip flop sets all data bus bits to a "1" during RD time indicating that a register has been updated. This transient condition may occur at the end of the Read Data strobe. Hence, invalid data may still be read from the clock, if the strobe width was less than 3 μ s.

TL/F/6681-2

The possibility may be overcome by implementing a further read of the tenths of seconds register at the end of every series of reads (starting with a read at the tenths of seconds register) and checking for unchanged data.

SECONDS COUNTERS

There are three counters for Seconds:

- tenths of seconds
- units of seconds
- tens of seconds

The outputs of all three counters can be separately multiplexed on to the command 4-bit output bus. Table I shows the address decoding for each counter. All three counters are reset to zero by the start/stop F/F.

MINUTES COUNTERS

There are two Minutes counters:

- units of minutes
- tens of minutes

Both counters are parallel loaded with data from the 4-bit input bus when addressed by the microprocessor and a Write Data Strobe pulse given. Similarly, the output of both counters can be read separately onto the common 4-bit output bus (Table I).

HOURS COUNTERS

There are two Hours counters which will count in a 24-hour mode:

- units of hours
- tens of hours

Both counters have identical parallel load and read multiplex features to the Minutes counters.

SEVEN DAY COUNTER

There is a 7-state counter which increments every 24 hours. It will have identical parallel load and read multiplex capabilities to the Minutes and Hours counters. The counter counts cyclically from 1–7.

Circuit Description (Continued)

FIGURE 2. Crystal Oscillator

DAYS COUNTER

There are two Days counters:

- units of days
- tens of days

The Days counters will count up to 28, 29, 30, or 31 days depending on the state of the Months counters and the Years Status Register. Days counters have parallel load and read multiplex capabilities.

MONTHS COUNTERS

There are two Months counters:

- units of months
- tens of months

The Months counters have parallel load and read multiplex capabilities.

YEARS STATUS REGISTER

The Years Status register is a shift register of 4 bits. It will be shifted every year on December 31st. The status register must be set in accordance with Table III. No readout capability is provided.

CHIP SELECT (CS)

An external chip select is provided. The chip enable is active low.

COUNTER AND REGISTER SELECTION

Table I shows the coding on the address lines AD0-AD3 which select the registers in the circuit to be either parallel loaded or read on to the output bus.

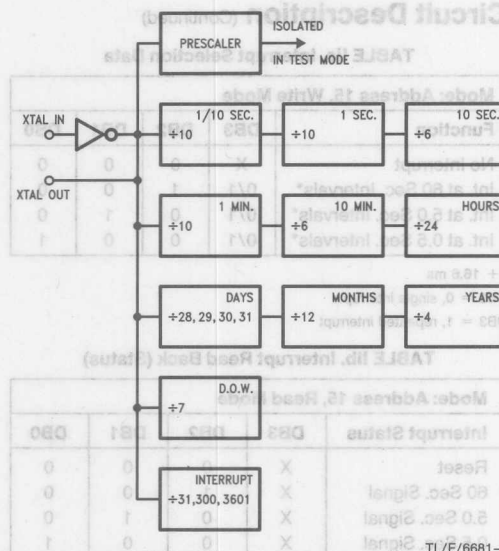

FIGURE 3. Test Mode Organization

START/STOP (RESET) LATCH

A logic "1" on DB0 at chip address 14 (E) will start the clock running, a logic "0" will stop the clock. This function allows the loading of time data into the clock and its precise starting. The clock starts at 0.1 seconds.

TEST MODE

This mode is incorporated to facilitate production testing of the circuit. In this mode, the 32,768 Hz clock is fed forward as shown in Figure 3. For normal operation, the circuit must be set to the non-test mode as part of the system initialization. This is accomplished by writing a logic "0" to DB3 at AD0.

TABLE I. Address Decoding for Internal Registers

Selected Counter	Address Bits				Mode
	AD3	AD2	AD1	AD0	
0 Test Only	0	0	0	0	Write Only
1 Tenths of Secs.	0	0	0	1	Read Only
2 Units of Secs.	0	0	1	0	Read Only

Leap Year-2	0	0	1	0
Leap Year-3	0	0	0	1

Note: Leap year counter rolls over on December 31 @ 23:59:59.

INTERRUPT SYSTEM

The interrupt output and its frequency of operation is enabled by writing to address 15 (see Table IIa). To ensure correct operation, the interrupt should be serviced within 16.6 ms.

The interrupt is initialized by writing "0" to address 15 and reading the interrupt, i.e., reading at address 15 three times. Initialization must be performed at power on and also if the interrupt is not serviced correctly within 16.6 ms.

SERVICING THE INTERRUPT

In a typical system the open drain interrupt output is wired to the processor interrupt system. Hence, when the interrupt timer times out, the interrupt output is pulled low and the processor is interrupted.

The processor may then reset the interrupt by utilizing the following procedure:

Read Address 15 three times.

This resets the interrupt output and restarts the interrupt timer when in the repeat mode.

It is recommended that the interrupt output is connected to a unique processor port.

CRYSTAL PARAMETERS

Figure 4 is an electrical representation of the crystal along with some typical values. The 32.768 kHz crystal is an NT CUT (tuning fork type) or XY BAR for use in a parallel resonant Pierce oscillator.

FIGURE 4. Typical Crystal Parameters

DEVICE INITIALIZATION AND OSCILLATOR SETTING

When first installed or if the battery back-up has failed, the MM58174A will require to be properly initialized. The following sequence is a suggested flow of operations to achieve this.

- | Action | Result |
|------------------------------------|---|
| 1) Apply power. | Clears interrupt timer chain. |
| 2) Write "0" to address 15. | |
| 3) Read 3 times from address 15. | Clears interrupt output logic. |
| 4) Write "0" on DB3 to address 0. | Clears test mode. |
| 5) Write "0" on DB0 to address 14. | Stops clock running. |
| 6) Set up timekeeping registers. | Load real-time into device time registers, minutes to leap years. |
| 7) Write "1" on DB0 to address 14. | Starts timekeeping synchronized to an external time source. |
| 8) Program and start interrupts. | Commence interrupt timing, if so required. |

OSCILLATOR SETTING

Directly connecting a frequency meter to the Crystal Out pin (14) will not allow correct frequency setting because of the extra capacitive loading of the meter. One possibility for setting is to use a high impedance probe or a CMOS buffer to keep the loading as low as possible (e.g., 100 x 2 pF probe). Alternatively, a buffered output of 16.384 kHz OSC/2 can be produced on DB0 by applying the following procedure:

- | Action | Result |
|---|--------------------------------|
| 1) Write a "1" on DB3 to address 0. | Selects test mode. |
| 2) Write a "1" on DB0 to address 14. | Starts clock timing. |
| 3) Read at address 1 (tenths of secs). | "Data Changed" signal is read. |
| 4) Read at address 1 and HOLD the strobe LOW. | 16.384 kHz appears on DB0. |
| 5) Adjust trimmer capacitor. | |

There must be no extra activity on the \overline{RD} line between steps 3 and 4 or only the normal "Data Changed" signal will be observed on the data bus. Thus if the normal host processor system is being used to generate the chip waveforms, proper care must be taken.

Timing Waveforms

READ MODE

Figure 6 gives detailed timing for the transfer of data from peripheral to microprocessor. See Table IV.

All times are measured from (or to) valid logic "0" level = 0.8V or valid logic "1" level = 2.0V.

MM58167B Microprocessor Real Time Clock

General Description

The MM58167B is a low threshold metal gate CMOS circuit that functions as a real time clock in bus oriented microprocessor systems. The device includes an addressable real time counter, 56 bits of RAM, and two interrupt outputs. A POWER DOWN input allows the chip to be disabled from the rest of the system for standby low power operation. The time base is a 32.768 Hz crystal oscillator.

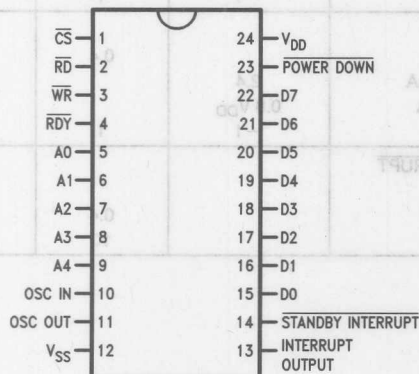

Features

- Microprocessor compatible (8-bit data bus)
- Milliseconds through month counters

- 56 bits of RAM with comparator to compare the real time counter to the RAM data
- 2 INTERRUPT OUTPUTS with 8 possible interrupt signals
- POWER DOWN input that disables all inputs and outputs except for one of the interrupts
- Status bit to indicate rollover during a read
- 32.768 Hz crystal oscillator
- Four-year calendar (no leap year)
- 24-hour clock

Functional Description

Real Time Counter

The real time counter is divided into 4-bit digits with 2 digits being accessed during any read or write cycle. Each digit represents a BCD number and is defined in Table I. Any unused bits are held at a logical zero during a read and ignored during a write. An unused bit is any bit not necessary to provide a full BCD number. For example tens of hours cannot legally exceed the number 2, thus only 2 bits are necessary to define the tens of hours. The other 2 bits in the tens of hours digit are unused. The unused bits are designated in Table I as dashes.

The addressable portion of the counter is from milliseconds to months. The counter itself is a ripple counter. The ripple delay is less than 60 μ s above 4.5V and 300 μ s at 2.2V.

RAM

56 bits of RAM are contained on-chip. These can be used for any necessary power down storage or as an alarm latch for comparison to the real time counter. The data in the RAM can be compared to the real time counter on a digit basis. The only digits that are not compared are the unit ten thousandths of seconds and tens of days of the week (these are unused in the real time counter). If the two most significant bits of any RAM digit are ones, then this RAM location will always compare. The rule of thumb for an "alarm" interrupt is: All nibbles of higher order than specified are set to C hex (always compare). All nibbles lower than specified are set to "zero". As an example, if an alarm is to occur everyday at 10:15 a.m., configure the bits in RAM as shown in Table II.

The RAM is formatted the same as the real time counter, 4 bits per digit, 14 digits, however there are no unused bits.

The unused bits in the real time counter will compare only to zeros in the RAM.

An address map is shown in Table III.

Interrupts and Comparator

There are two interrupt outputs. The first is the INTERRUPT OUTPUT (a true high signal). This output can be programmed to provide 8 different output signals. They are: 10 Hz, once per second, once per minute, once per hour, once a day, once a week, once a month, and when a RAM/real time counter comparison occurs. To enable the output a one is written into the interrupt control register at the bit location corresponding to the desired output frequency (Figure 1). Once one or more bits have been set in the interrupt control register, the corresponding counter's rollover to its reset state will clock the interrupt status register and cause the interrupt output to go high. To reset the interrupt and to identify which frequency caused the interrupt, the interrupt status register is read. Reading this register places the contents of the status register on the data bus. The interrupting frequency will be identified by a one in the respective bit position. Removing the read will reset the interrupt.

The second interrupt is the STANDBY INTERRUPT (open drain output, active low). This interrupt occurs when enabled and when a RAM/real time counter comparison occurs. The STANDBY INTERRUPT is enabled by writing a one on the D0 line at address 16H or disabled by writing a zero on the D0 line. This interrupt is not triggered by the edge of the compare signal, but rather by the level. Thus if the compare is enabled when the STANDBY INTERRUPT is enabled, the interrupt will turn on immediately.

TABLE I. Real Time Counter Format

1	0	1	0	0	Status Bit
1	0	1	0	1	GO Command
1	0	1	1	0	STANDBY INTERRUPT
1	1	1	1	1	Test Mode

All others unused

The comparator is a cascaded exclusive NOR. Its output is latched 61 μ s after the rising edge of the 1 kHz clock signal (input to the milliseconds counter). This allows the counter to ripple through before looking at the comparator. For operation at less than 4.5V, the thousandths of seconds counter should not be included in a compare because of the possibility of having a ripple delay greater than 61 μ s. (For output timing see Interrupt Timing.)

Power Down Mode

The **POWER DOWN** input is essentially a second chip select. It disables all inputs and outputs except for the **STANDBY INTERRUPT**. When this input is at a logical zero, the device will not respond to any external signals. It will, however, maintain timekeeping and turn on the **STANDBY INTERRUPT** if programmed to do so. (The programming must be done before the **POWER DOWN** input goes to a

Functional Description (Continued)

logical zero.) When switching V_{DD} to the standby or power down mode, the POWER DOWN input should go to a logical zero at least 1 μ s before V_{DD} is switched. When switching V_{DD} all other inputs must remain between $V_{SS} - 0.3V$ and $V_{DD} + 0.3V$. When restoring V_{DD} to the normal operating mode, it is necessary to insure that all other inputs are at valid levels before switching the POWER DOWN input back to a logical one. These precautions are necessary to insure that no data is lost or altered when changing to or from the power down mode.

Counter and RAM Resets; GO Command

The counters and RAM can be reset by writing all 1's (FF) at address 12_H or 13_H respectively.

A write pulse at address 15_H will reset the thousandths, hundredths, tenths, units, and tens of seconds counters. This GO command is used for precise starting of the clock. The data on the data bus is ignored during the write. If the seconds counter is at a value greater than 39 when the GO is issued, the minute counter will increment; otherwise the minute counter is unaffected. This command is not necessary to start the clock, but merely a convenient way to start precisely at a given minute.

Status Bit

The status bit is provided to inform the user that the clock is in the process of rolling over when a counter is read. The status bit is set if this 1 kHz clock occurs during or after any counter read. This tells the user that the clock is rippling through the real time counter. Because the clock is rippling, invalid data may be read from the counter. If the status bit is set following a counter read, the counter should be reread.

The status bit appears on D0 when address 14_H is read. All the other data lines will zero. The bit is set when a logical one appears. This bit should be read every time a counter read or after a series of counter reads are done. The trailing edge of the read at address 14_H will reset the status bit.

Using the Rollover Status Bit

If a single read of any clock counter is made, it should be followed by reading the rollover status bit.

Example: Read months, then read rollover status.

If a sequential read of the clock counters is made, then the rollover status bit should be read after the last counter is read.

Example: Read hours, minutes, seconds, then read the rollover status.

Oscillator

The oscillator used in the standard Pierce parallel resonant oscillator. Externally, 2 capacitors, a 20 M Ω resistor and the crystal are required. The 20 M Ω resistor is connected between OSC IN and OSC OUT to bias the internal inverter in the linear region. For micropower crystals a resistor in series with the oscillator output may be necessary to insure the crystal is not overdriven. This resistor should be approximately 200 k Ω . The capacitor values should be typically 20 pF–25 pF. The crystal frequency is 32,768 Hz.

The oscillator input can be externally driven, if desired. In this case the oscillator output should be left floating and the oscillator input levels should be within 0.3V of the supplies.

A ground line or ground plane between pins 9 and 10 may be necessary to reduce interference of the oscillator by the A4 address.

Control Lines

The READ, WRITE, AND CHIP SELECT signals are active low inputs. The READY signal is an open drain output. At the start of each read or write cycle the READY line (open drain) will pull low and will remain low until valid data from a chip read appears on the bus or data on the bus is latched in during a write. READ and WRITE must be accompanied by a CHIP SELECT (see Figures 3 and 4 for read and write cycle timing).

During a read or write, address bits must not change while chip select and control strobes are low.

Test Mode

The test mode is for production testing. It allows the counters to count at a higher than normal rate. In this mode the 32.768 kHz oscillator input is connected directly to the ten thousandths of seconds counter. The chip select and write lines must be low and the address must be held at 1F_H.

NS32FX211 Microprocessor Compatible Real Time Clock

General Description

The NS32FX211 is fabricated using low threshold CMOS technology and is designed to operate in bus oriented microprocessor systems where a real time clock and calendar function are required. The on-chip 32.768 kHz crystal controlled oscillator will maintain timekeeping down to 2.2V to allow low power standby battery operation.

Applications

- Fax machines
- Laser printers
- Word processors
- Data logging
- Industrial process control

Features

- Low power standby operation (10 μ A at 2.2V)
- 16-pin DIP and 20-pin PLCC
- Timekeeping from tenths to seconds to tens of years in independently accessible registers
- Leap year register
- Hours counter programmable for 12 or 24-hour operation
- Fully TTL/CMOS compatible

t _{WD}	Data Bus Hold Time Following Write Strobe 	100	35		ns
t _{AWS}	Address Bus Valid before Start or Write Strobe	70	20		ns

Note 3: Except for special case restriction: with interrupts programmed, max read strobe width of control register (ADDR 0) is 30 ms. See section on Interrupt Programming.

Note 4: All timings measured to the trailing edge of write strobe (data latched by the trailing edge of \overline{WR}).

Note 5: Input test waveform peak voltages are 2.4V and 0.4V. Output signals are measured to their 2.4V and 0.4V levels.

Note 6: Write strobe as used in the Write Timing Table is defined as the period when both chip select and write inputs are low, i.e., $\overline{WS} = \overline{CS} + \overline{WR}$. Hence write strobe commences when both signals are low, and terminates when the first signal returns high.

Note 7: Read strobe as used in the Read Timing Table is defined as the period when both chip select and read inputs are low, i.e., $\overline{RS} = \overline{CS} + \overline{RD}$.

Note 8: Typical numbers are at $V_{CC} = 5.0V$ and $T_A = 25^\circ\text{C}$.

FIGURE 2

Functional Description

The NS32FX211 is a bus oriented microprocessor real time clock.

Crystal Oscillator

This consists of a CMOS inverter/amplifier with an on-chip bias resistor. Externally a 22 pF capacitor, a 6 pF-40 pF trimmer capacitor and a crystal are suggested to complete the 32.768 kHz timekeeping oscillator circuit.

The 6 pF-40 pF trimmer fine tunes the crystal load impedance, optimizing the oscillator stability. When properly adjusted (i.e., to the crystal frequency of 32.768 kHz), the circuit will display a frequency variation with voltage of less than 3 ppm/V. When an external oscillator is used, connect to oscillator input and float (no connection) the oscillator output.

When the chip is enabled into test mode, the oscillator is gated onto the interrupt output pin giving a buffered oscillator output that can be used to set the crystal frequency when the device is installed in a system.

Divider Chain

The crystal oscillator is divided down in three stages to produce a 10 Hz frequency setting pulse. The first stage is a non-integer divider which reduces the 32.768 kHz input to 20.720 kHz. This is further divided by a 9-stage binary ripple counter giving an output frequency of 60 Hz. A 3-stage

Johnson counter divides this by six, generating a 10 Hz output. The 10 Hz clock is gated with the 32.768 kHz crystal frequency to provide clock setting pulses of 15.26 μ s duration. The setting pulse drives all the time registers on the device which are synchronously clocked by this signal. All time data and data-changed flag change on the falling edge of the clock setting pulse.

Data-Changed Flag

The data-changed flag is set by the clock setting pulse to indicate that the time data has been altered since the clock was last read. This flag occupies bit 3 of the control register where it can be tested by the processor to sense data-changed. It will be reset by a read of the control register. See the section, "Methods of Device Operation", for suggested clock reading techniques using this flag.

Seconds Counters

There are three counters for seconds:

- tenths of seconds
- units of seconds
- tens of seconds

The registers are accessed at the addresses shown in Table I. The tenths of seconds register is reset to 0 when the clock start/stop bit (bit 2 of the control register) is set to

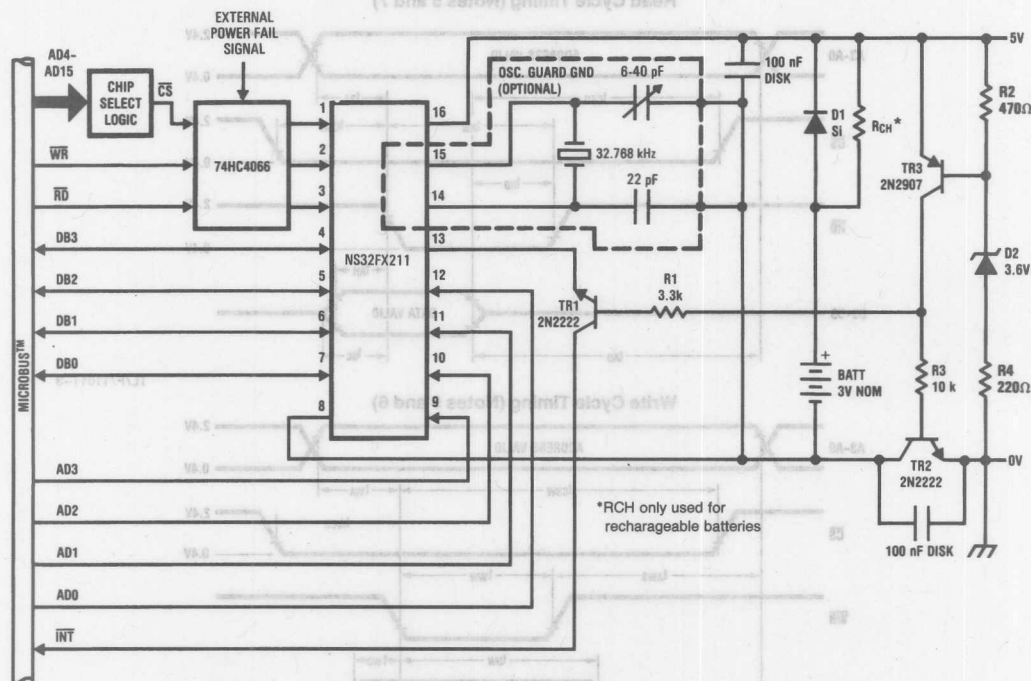

FIGURE 3. Typical System Connection Diagram

TL/F/11011-5

logic 1. The units and tens of seconds are set up by the processor, giving time setting to the nearest second. All three registers can be read by the processor for time output.

Minutes Counters

There are two minutes counters:

- units of minutes
- tens of minutes

Both registers may be read to or written from as required.

Hours Counters

There are two hours counters:

- units of hours
- tens of hours

Both counters may be accessed for read or write operations as desired.

In 12-hour mode, the tens of hours register has only one active bit and the top three bits are set to logic 0. Data bit 1 of the clock setting register is the AM/PM indicator; logic 0 indicating AM, logic 1 for PM.

When 24-hour mode is programmed, the tens of hours register reads out two bits of data and the two most significant bits are set to logic 0. There is no AM/PM indication and bit 1 of the clock setting register will read out a logic 0.

In both 12/24-hour modes, the units of hours will read out four active data bits. 12 or 24-hour mode is selected by bit 0

of the clock setting register, logic 0 for 12-hour mode, logic 1 for the 24-hour mode.

Days Counters

There are two days counters:

- units of day
- tens of days

The days counters will count up to 28, 29, 30 or 31 depending on the state of the months counters and the leap year counter. The microprocessor has full read/write access to these registers.

Months Counters

There are two months counters:

- units of months
- tens of months

Both these counters have full read/write access.

Years Counters

There are two years counters:

- units of years
- tens of years

Both these counters have full read/write access. The years will count up to 99 and roll over to 00.

Functional Description (Continued)

TABLE I. Address Decoding of Real-Time Clock Internal Registers

Registered Select	Address (Binary)				(Hex)	Access
	AD3	AD2	AD1	AD0		
0 Control Register	0	0	0	0	0	Split Read and Write
1 Tenths of Seconds	0	0	0	1	1	Read Only
2 Units Seconds	0	0	1	0	2	R/W
3 Tens Seconds	0	0	1	1	3	R/W
4 Units Minutes	0	1	0	0	4	R/W
5 Tens Minutes	0	1	0	1	5	R/W
6 Unit Hours	0	1	1	0	6	R/W
7 Tens Hours	0	1	1	1	7	R/W
8 Units Days	1	0	0	0	8	R/W
9 Tens Days	1	0	0	1	9	R/W
10 Units Months	1	0	1	0	A	R/W
11 Tens Months	1	0	1	1	B	R/W
12 Units Years	1	1	0	0	C	R/W
13 Tens Years	1	1	0	1	D	R/W
14 Days of Week	1	1	1	0	E	R/W
15 Clock Setting/ Interrupt Registers	1	1	1	1	F	R/W

Day of Week Counter

The day of week counter increments as the time rolls from 23:59 to 00:00 (11:59 PM to 12:00 AM in 12-hour mode). It counts from 1 to 7 and rolls back to 1. Any day of the week may be specified as day 1.

Clock Setting Register/Interrupt Register

The interrupt select bit in the control register determines which of these two registers is accessible to the processor at address 15. Normal clock and interrupt timing operations will always continue regardless of which register is selected onto the bus. The layout of these registers is shown in Table II.

The clock setting register is comprised of three separate functions:

- leap year counter: bits 2 and 3
- AM/PM indicator: bit 1
- 12/24-hour mode set: bit 0 (see Table IIA).

The leap year counter is a 2-stage binary counter which is clocked by the months counter. It changes state as the time rolls over from 11:59 on December 31 to 00:00 on January 1.

The counter should be loaded with the 'number of years since last leap year' e.g., if 1980 was the last leap year, a clock programmed in 1983 should have 3 stored in the leap year counter. If the clock is programmed during a leap year, then the leap year counter should be set to 0. The contents of the leap year counter can be read by the μ P.

The AM/PM indicator returns a logic 0 for AM and a logic 1 for PM. It is clocked when the hours counter rolls from 11:59 to 12:00 in 12-hour mode. In 24-hour mode this bit is set to logic 0.

The 12/24-hour mode set determines whether the hours counter counts from 1 to 12 or from 0 to 23. It also controls the AM/PM indicator, enabling it for 12-hour mode and forcing it to logic 0 for the 24-hour mode. The 12/24-hour mode bit is set to logic 0 for 12-hour mode and it is set to logic 1 for 24-hour mode.

IMPORTANT NOTE: Hours mode and AM/PM bits cannot be set in the same write operation. See the section on Initialization (Methods of Device Operation) for a suggested setting routine.

All bits in the clock setting register may be read by the processor.

The interrupt register controls the operation of the timer for interrupt output. The processor programs this register for single or repeated interrupts at the selected time intervals.

The lower three bits of this register set the time delay period that will occur between interrupts. The time delays that can be programmed and the data words that select these are outlined in Table IIB.

Data bit 3 of the interrupt register sets for either single or repeated interrupts; logic 0 gives single mode, logic 1 sets for repeated mode.

Using the interrupt is described in the Device Operation section.

Functional Description (Continued)

TABLE IIA. Clock Setting Register Layout

Function	Hex	Data Bits Used				Comments	Access
		DB3	DB2	DB1	DB0		
Leap Year Counter	0	X	X	0	0	0 Indicates a Leap Year	R/W
AM/PM Indicator (12-Hour Mode)	1	0	0	X	0	0 = AM 1 = PM	R/W
	2	0	0	0	0	0 in 24-Hour Mode	R/W
	3	0	0	1	0	0 = 12-Hour Mode	R/W
12/24-Hour Select Bit	4	0	0	0	X	1 = 24-Hour Mode	R/W

TABLE IIB. Interrupt Control Register

Function	Comments	Control Word			
		DB3	DB2	DB1	DB0
No Interrupt	Interrupt Output Cleared, Start/Stop Bit Set to 1.	X	0	0	0
0.1 Second		0/1	0	0	1
0.5 Second		0/1	0	1	0
1 Second		0/1	0	1	1
5 Seconds	DB3 = 0 for Single Interrupt	0/1	1	0	0
10 Seconds	DB3 = 1 for Repeated Interrupt	0/1	1	0	1
30 Seconds		0/1	1	1	0
60 Seconds		0/1	1	1	1

Timing Accuracy: Single Interrupt Mode (all time delays): ± 1 ms

Repeated Mode: ± 1 ms on Initial Timeout, Thereafter Synchronous with First Interrupt (i.e., timing errors do not accumulate).

Control Register

There are three registers which control different operations of the clock:

- the clock setting register
- the interrupt register
- the control register

The clock setting and interrupt registers both reside at address 15, access to one or the other being controlled by the interrupt select bit; data bit 1 of the control register.

The clock setting register programs the timekeeping of the clock. The 12/24-hour mode select and the AM/PM indicator for 12-hour mode occupy bits 0 and 1, respectively. Data bits 2 and 3 set the leap year counter.

The interrupt register controls the operation of the interrupt timer, selecting the required delay period and either single or repeated interrupt.

The control register is responsible for controlling the operations of the clock and supplying status information to the processor. It appears as two different registers; one with write only access and one with read only access.

The write only register consists of a bank of four latches which control the internal processes of the clock.

The read only register contains two output data latches which will supply status information for the processor. Table III shows the mapping of the various control latches and status flags in the control register. The control register is located at address 0.

The write only portion of the control register contains four latches:

A logic 1 written into the test bit puts the device into test mode. This allows setting of the oscillator frequency. For normal operation the test bit is loaded with logic 0.

The clock start/stop bit stops the timekeeping of the clock and resets to 0 the tenths of seconds counter. The time of day may then be written into the various clock registers and the clock restarted synchronously with an external time source. Timekeeping is maintained thereafter.

A logic 1 written to the start/stop bit halts clock timing. Timing is restarted when the start/stop bit is written with a logic 0.

The interrupt select bit determines which of the two registers mapped onto address 15 will be accessed when this address is selected.

A logic 0 in the interrupt select bit makes the clock setting register available to the processor. A logic 1 selects the interrupt register.

The interrupt start/stop bit controls the running of the interrupt timer. It is programmed in the same way as the clock start/stop bit; logic 1 to halt the interrupt and reset the timer, logic 0 to start interrupt timing.

When no interrupt is programmed (interrupt control register set to 0), the interrupt start/stop bit is automatically set to a logic 1. When any new interrupt is subsequently programmed, timing will not commence until the start/stop bit is loaded with 0.

In the single interrupt mode, interrupt timing stops when a timeout occurs. The processor restarts timing by writing logic 0 into the start/stop bit.

In repeated interrupt mode the interrupt timer continues to count with no intervention by the processor necessary.

Functional Description (Continued)

TABLE III. The Control Register Layout

Access (addr0)	DB3	DB2	DB1	DB0
Read From:	Data-Changed Flag	0	0	Interrupt Flag
Write To:	Test 0 = Normal 1 = Test Mode	Clock Start/Stop 0 = Clock Run 1 = Clock Stop	Interrupt Select 0 = Clock Setting Register 1 = Interrupt Register	Interrupt Start/Stop 0 = Interrupt Run 1 = Interrupt Stop

Interrupt timing may be stopped in either mode by writing a logic 1 into the interrupt start/stop bit. The timer is reset and can be restarted in the normal way, giving a full time delay period before the next interrupt.

In general, the control register is set up such that writing 0's into it will start anything that is stopped, pull the clock out of test mode and select the clock setting register onto the bus. In other words, writing 0 will maintain normal clock operation and restart interrupt timing, etc.

The read only portion of the control register has two status outputs:

Since the NS32FX211 keeps real time, the time data changes asynchronously with the processor and this may occur while the processor is reading time data out of the clock.

Some method of warning the processor when the time data has changed must thus be included. This is provided for by the data-changed flag located in bit 3 of the control register. This flag is set by the clock setting pulse which also clocks the time registers. Testing this bit can tell the processor whether or not the time has changed. The flag is cleared by a read of the control register but not by any write operations. No other register read has any effect on the state of the data-changed flag.

Data bit 0 is the interrupt flag. This flag is set whenever the interrupt timer times out, pulling the interrupt output low. In a polled interrupt routine the processor can test this flag to determine if the NS32FX211 was the interrupting device. This interrupt flag and the interrupt output are both cleared by a read of the control register.

Both of the flags and the interrupt output are reset by the trailing edge of the read strobe. The flag information is held latched during a control register read, guaranteeing that stable status information will always be read out by the processor.

Interrupt timeout is detected and stored internally if it occurs during a read of the control register, the interrupt output will then go low only after the read has been completed.

A clock setting pulse occurring during a control register read will not affect the data-changed flag since time data read out before or after the control read will not be affected by the time change.

Initialization

When it is first installed and power is applied, the NS32FX211 will need to be properly initialized. The following operation steps are recommended when the device is set up (all numbers are decimal):

1) Disable interrupt on the processor to allow oscillator setting. Write 15₁₀ into the control register: *The clock and interrupt start/stop bits are set to 1, ensuring that the clock and interrupt timers are both halted. Test mode and the interrupt register are selected.*

2) Write 0 to the interrupt register: *Ensure that there are no interrupts programmed and that the oscillator will be gated onto the interrupt output.*

3) Set oscillator frequency: *All timing has been halted and the oscillator is buffered out onto the interrupt line.*

4) Write 5 to the control register: *The clock is now out of test mode but is still halted. The clock setting register is now selected by the interrupt select bit.*

5) Write 0001 to all registers. This ensures starting with a valid BCD value in each register.

6) Set 12/24 Hours Mode: *Write to the clock setting register to select the hours counting mode required.*

7) Load Real-Time Registers: *All time registers (including Leap Years and AM/PM bit) may now be loaded in any order. Note that when writing to the clock setting register to set up Leap Years and AM/PM, the Hours Mode bit must not be altered from the value programmed in step 5.*

8) Write 0 to the control register: *This operation finishes the clock initialization by starting the time. The final control register write should be synchronized with an external time source.*

In general, timekeeping should be halted before the time data is altered in the clock. The data can, however, be altered at any time if so desired. Such may be the case if the user wishes to keep the clock corrected without having to stop and restart it; i.e., winter/summer time changing can be accomplished without halting the clock. This can be done in software by sensing the state of the data-changed flag and only altering time data just after the time has rolled over (data-changed flag set).

Reading the Time Registers

Using the data-changed flag technique supports microprocessors with block move facilities, as all the necessary time data may be read sequentially and then tested for validity as shown below.

1) Read the control register, address 0: *This is a dummy read to reset the data-changed flag (DCF) prior to reading the time registers.*

2) Read time registers: *All desired time registers are read out in a block.*

3) Read the control register and test DCF: *If DCF is cleared (logic 0), then no clock setting pulses have after occurred since step 1. All time data is guaranteed good and time reading is complete.*

If DCF is set (logic 1), then a time change has occurred since step 1 and time data may not be consistent. Repeat steps 2 and 3 until DCF is clear. The control read of step 3 will have reset DCF, automatically repeating the step 1 action.

Functional Description (Continued)

Interrupt Programming

The interrupt timer generates interrupts at time intervals which are programmed into the interrupt register. A single interrupt after delay or repeated interrupts may be programmed. Table IIB lists the different time delays and the data words that select them in the interrupt register.

Once the interrupt register has been used to set up the delay time and to select for single or repeat, it takes no further part in the workings of the interrupt system. All activity by the processor then takes place in the control register. Initializing:

- 1) Write 3 to the control register (AD0): *Clock timing continues, interrupt register selected and interrupt timing stopped.*
- 2) Write interrupt control word to address 15: *The interrupt register is loaded with the correct word (chosen from Table IIB) for the time delay required and for single or repeated interrupts.*
- 3) Write 0 or 2 to the control register: *Interrupt timing commences. Writing 0 selects the clock setting register onto the data bus; writing 2 leaves the interrupt register selected. Normal timekeeping remains unaffected.*

On Interrupt:

Read the control register and test for Interrupt Flag (bit 0).

If the flag is cleared (logic 0), then the device is not the source of the interrupt.

If the flag is set (logic 1), then the clock did generate an interrupt. The flag is reset and the interrupt output is cleared by the control register read that was used to test for interrupt.

Single Interrupt Mode:

When appropriate, write 0 or 2 to the control register to restart the interrupt timer.

Repeated Interrupt Mode:

Timing continues, synchronized with the control register write which originally started interrupt timing. No further intervention is necessary from the processor to maintain timing.

In either mode interrupt timing can be stopped by writing 1 into the control register (interrupt start/stop set to 1). Timing for the full delay period recommences when the interrupt start/stop bit is again loaded with 0 as normal.

IMPORTANT NOTE: Using the interrupt timer places a constraint on the maximum Read Strobe width which may be applied to the clock. Normally all registers may be read from with a t_{RW} down to DC (i.e., \overline{CS} and \overline{RD} held continuously low). When the interrupt timer is active however, the maximum read strobe width that can be applied to the control register (Addr 0) is 30 ms.

This restriction is to allow the interrupt timer to properly reset when it times out. Note that it only affects reading of the control register—all other addresses in the clock may be accessed with DC read strobes, regardless of the state of the interrupt timer. Writes to any address are unaffected.

APPLICATION HINTS

Time Reading Using Interrupt

In systems such as point of sale terminals and data loggers, time reading is usually only required on a random demand basis. Using the data-changed flag as outlined in the section on methods of operation is ideal for this type of system. Some systems, however, need to sense a change in real time; e.g., industrial timers/process controllers, TV/VCR clocks, any system where real time is displayed.

The interrupt timer on the NS32FX211 can generate interrupts synchronously with the time registers changing, using software to provide the initial synchronization.

In single interrupt mode the processor is responsible for initiating each timing cycle and the timed period is accurate to ± 1 ms.

In repeated interrupt mode the period from the initial processor start to the first timeout is also only accurate to ± 1 ms. The following interrupts maintain accurate delay periods relative to the first timeout. Thus, to utilize interrupt to control time reading, we will use repeated interrupt mode.

In repeated mode the time period between interrupts is exact, which means that timeouts will always occur at the same point relative to the internal clock setting pulses. The case for 0.1s interrupts is shown in Figure A-1. The same is true for other delay periods, only there will be more clock setting pulses between each interrupt timeout. If we set up the interrupt timer so that interrupt always times out just after the clock setting pulse occurs (Figure A-2), then there is no need to test the data-changed flag as we know that the time data has just changed and will not alter again for another 100 ms.

This can be achieved as outlined below:

- 1) Follow steps 1 and 2 of the section on interrupt programming. In step 2 set up for repeated interrupt.
- 2) Read control register AD0: *This is a dummy read to reset the data-changed flag.*
- 3) Read control register AD0 until data-changed flag is set.
- 4) Write 0 or 2 to control register. Interrupt timing commences.

Time Reading with Very Slow Read Cycles

If a system takes longer than 100 ms to complete reading of all the necessary time registers (e.g., when CMOS processors are used) or where high level interpreted language routines are used, then the data-changed flag will always be set when tested and is of no value. In this case, the time registers themselves must be tested to ensure data accuracy.

The technique below will detect both time changing *between* read strobes (i.e., between reading tens of minutes and units of hours) and also time changing *during* read, which can produce invalid data.

- 1) Read and store the value of the *lowest* order time register required.

Functional Description (Continued)

2) Read out all the time registers required. The registers may be read out in any order, simplifying software requirements.

3) Read the lowest order register and compare it with the value stored previously in step 1. If it is still the same, then all time data is good. If it has changed, then store the new value and go back to step 2.

In general, the rule is that the first and last reads *must* both be of the lowest order time register. These two values can then be compared to ensure that no change has occurred. This technique works because for any higher order time register to change, all the lower order registers must also change. If the lowest order register does not change, then no higher order register has changed either.

TL/F/11011-6

FIGURE A-1. Time Delay from Clock Setting Pulses to Interrupt is Constant

TL/F/11011-7

FIGURE A-2. Interrupt Timer Synchronized with Clock Setting Pulses

Functional Description (Continued)

2) Read out all the time registers required. The registers may be read out in any order, simplifying software requirements.

3) Read the lowest order register and compare it with the value stored previously in step 1. If it is still the same, then all time data is good. If it has changed, then store the new value and go back to step 2.

In general, the rule is that the first and last reads must both be of the lowest order time register. These two values can then be compared to ensure that no change has occurred. This technique works because for any higher order time register to change, all the lower order registers must also change. If the lowest order register does not change, then no higher order register has changed either.

MM58167B Real Time Clock Design Guide

National Semiconductor
Application Note 353
Milt Schwartz

The MM58167B is a real-time 24-hour format clock with input/output structure and control lines that facilitate interfacing to microprocessors. It provides a reliable source of calendar data from milliseconds through months, as well as 6 bytes plus 2 nibbles of RAM, which are available to the user if the alarm (compare) interrupt is not used. The MM58167B features low power consumption (typically 4.5 microamperes at 3-volt supply) during battery backed mode, flexible interrupt structure (alarm and repetitive), and a fast internal update rate (1 kHz). Systems utilizing this device include, personal computers, process control, security, and data acquisition.

This application note covers hardware interface to microprocessors, clock interrupts, oscillator operation, accuracy, calibration techniques, software, and battery back-up considerations.

Hardware Description Overview

1.0 Figure 1 is a functional block diagram of the MM58167B.

It can be subdivided into the following sections:

1.1 Oscillator

The oscillator consists of an internal inverter to which the user connects a 32.768 kHz crystal, bias resistor and capacitors, to form a Pierce parallel resonant circuit.

1.2 Prescaler

The prescaler divides the 32.768 kHz oscillator down to 1 kHz using pulse swallowing techniques. The 1 kHz pulse rate is the incrementing signal for the timekeeping counters.

Block Diagram

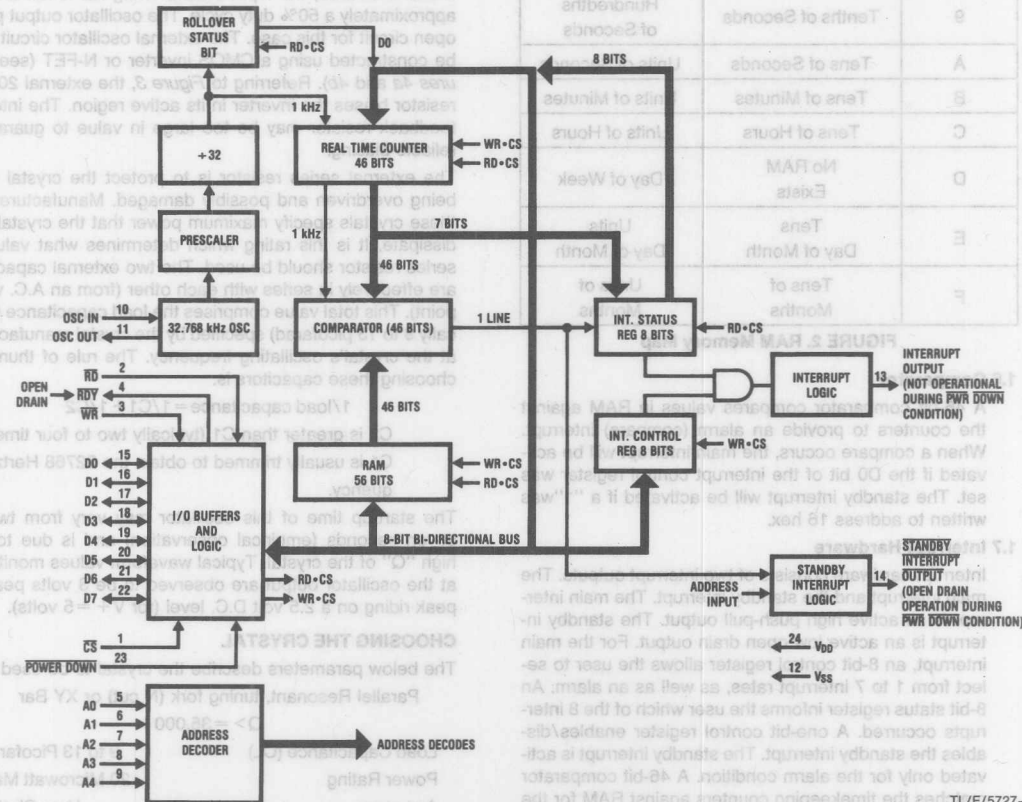

FIGURE 1

TU/F/5727-1

Hardware Description Overview (Continued)

1.3 Timekeeping Counters

The timekeeping section consists of a 14-stage BCD counter, each stage having read/write capability. The counters keep time in a 24-hour format. *Figure 6* shows the counter detail of calendar-date-time format.

1.4 Rollover Status

A rollover status bit (read only) informs the user that invalid data may have been read, due to the counters being incremented during a counter read or between successive counter reads. This situation occurs because the counters are clocked asynchronously with respect to the microprocessor.

1.5 RAM

14 nibbles of RAM are provided for alarm (compare) interrupt or general storage. The nibbles are packed 2 per address except for 2 locations, address 08 and 0D (HEX). The nibble at address 08 appears in the high order 4 bits, while the nibble at address 0D appears in the low order 4 bits. See memory map *Figure 2* for details.

Address In HEX	D7 D6 D5 D4	D3 D2 D1 D0
8	Milliseconds	No RAM Exists
9	Tenths of Seconds	Hundredths of Seconds
A	Tens of Seconds	Units of Seconds
B	Tens of Minutes	Units of Minutes
C	Tens of Hours	Units of Hours
D	No RAM Exists	Day of Week
E	Tens Day of Month	Units Day of Month
F	Tens of Months	Units of Months

FIGURE 2. RAM Memory Map

1.6 Comparator

A 46-bit comparator compares values in RAM against the counters to provide an alarm (compare) interrupt. When a compare occurs, the main interrupt will be activated if the D0 bit of the interrupt control register was set. The standby interrupt will be activated if a "1" was written to address 16 hex.

1.7 Interrupt Hardware

Interrupt hardware consists of two interrupt outputs. The main interrupt and the standby interrupt. The main interrupt is an active high push-pull output. The standby interrupt is an active low open drain output. For the main interrupt, an 8-bit control register allows the user to select from 1 to 7 interrupt rates, as well as an alarm. An 8-bit status register informs the user which of the 8 interrupts occurred. A one-bit control register enables/disables the standby interrupt. The standby interrupt is activated only for the alarm condition. A 46-bit comparator matches the timekeeping counters against RAM for the alarm interrupt.

1.8 Input/Output and Control Lines

The input/output structure consists of a 5-bit address bus and 8-bit bidirectional data bus. The control lines are chip select, power down, read and write. In addition, a ready output is provided for those microprocessors that have wait-state capability and meet the timing requirements of the ready signal. The power down input acts as a chip select of opposite polarity. It differs from the chip select in that it will TRI-STATE® the main interrupt output while the chip select does not TRI-STATE the interrupt. The power down input is intended to facilitate deselecting the chip for battery backed operation. Chip select, read and write are active low controls. The ready output is active low open drain and is caused by chip select and the negative-going-edge of read or write (it is an internal one-shot). If the ready output is not used as a control line when interfacing to a microprocessor, it may be left open circuit.

Detail Descriptions

OSCILLATOR

Figure 3 represents the internal and external circuitry that comprise the oscillator. The inverter, which is the heart of the oscillator, is designed to consume minimum power. The inverter has a typical gain of 30 at 1 kHz and 4 at 30 kHz. The oscillator input may be driven from an external source. If this is desired, the input should swing rail-to-rail and be approximately a 50% duty cycle. The oscillator output pin is open circuit for this case. The external oscillator circuit may be constructed using a CMOS inverter or N-FET (see *Figures 4a* and *4b*). Referring to *Figure 3*, the external 20 MΩ resistor biases the inverter in its active region. The internal feedback resistor may be too large in value to guarantee reliable biasing.

The external series resistor is to protect the crystal from being overdriven and possibly damaged. Manufacturers of these crystals specify maximum power that the crystal can dissipate. It is this rating which determines what value of series resistor should be used. The two external capacitors are effectively in series with each other (from an A.C. viewpoint). This total value comprises the load capacitance (typically 9 to 13 picofarad) specified by the crystal manufacturer at the crystal's oscillating frequency. The rule of thumb in choosing these capacitors is:

$$1/\text{load capacitance} = 1/C1 + 1/C2$$

C2 is greater than C1 (typically two to four times)

C1 is usually trimmed to obtain the 32768 Hertz frequency.

The start-up time of this oscillator may vary from two to seven seconds (empirical observation) and is due to the high "Q" of the crystal. Typical waveform values monitored at the oscillator output are observed to be 3 volts peak to peak riding on a 2.5 volt D.C. level (for V+ = 5 volts).

CHOOSING THE CRYSTAL

The below parameters describe the crystal to be used

Parallel Resonant, tuning fork (N cut) or XY Bar

$$Q > = 35,000$$

Load Capacitance (CL)	9 to 13 Picofarad
Power Rating	20 Microwatt Max.
Accuracy	User Choice
Temperature Coefficient	User Choice

Detail Descriptions (Continued)

FIGURE 5. Flow Chart for Calibration Using the 1 Hz Repetitive Interrupt

If the 32,768 Hertz is to be measured directly, then a HI impedance LO capacitance amplifier or comparator or CMOS gate should be connected to the oscillator output pin to prevent the measuring instrument from offsetting the frequency of the oscillator. This addition is permanently a part of the oscillator circuit and must be battery backed if the clock is battery backed. The reason for battery backing this buffer is to ensure that its input impedance does not change during the power down operation which could result in the oscillator stopping or being offset in frequency.

PRESCALER OPERATION

The 32,768 Hertz signal is divided to an even 32,000 Hertz using pulse swallowing techniques. This is accomplished by

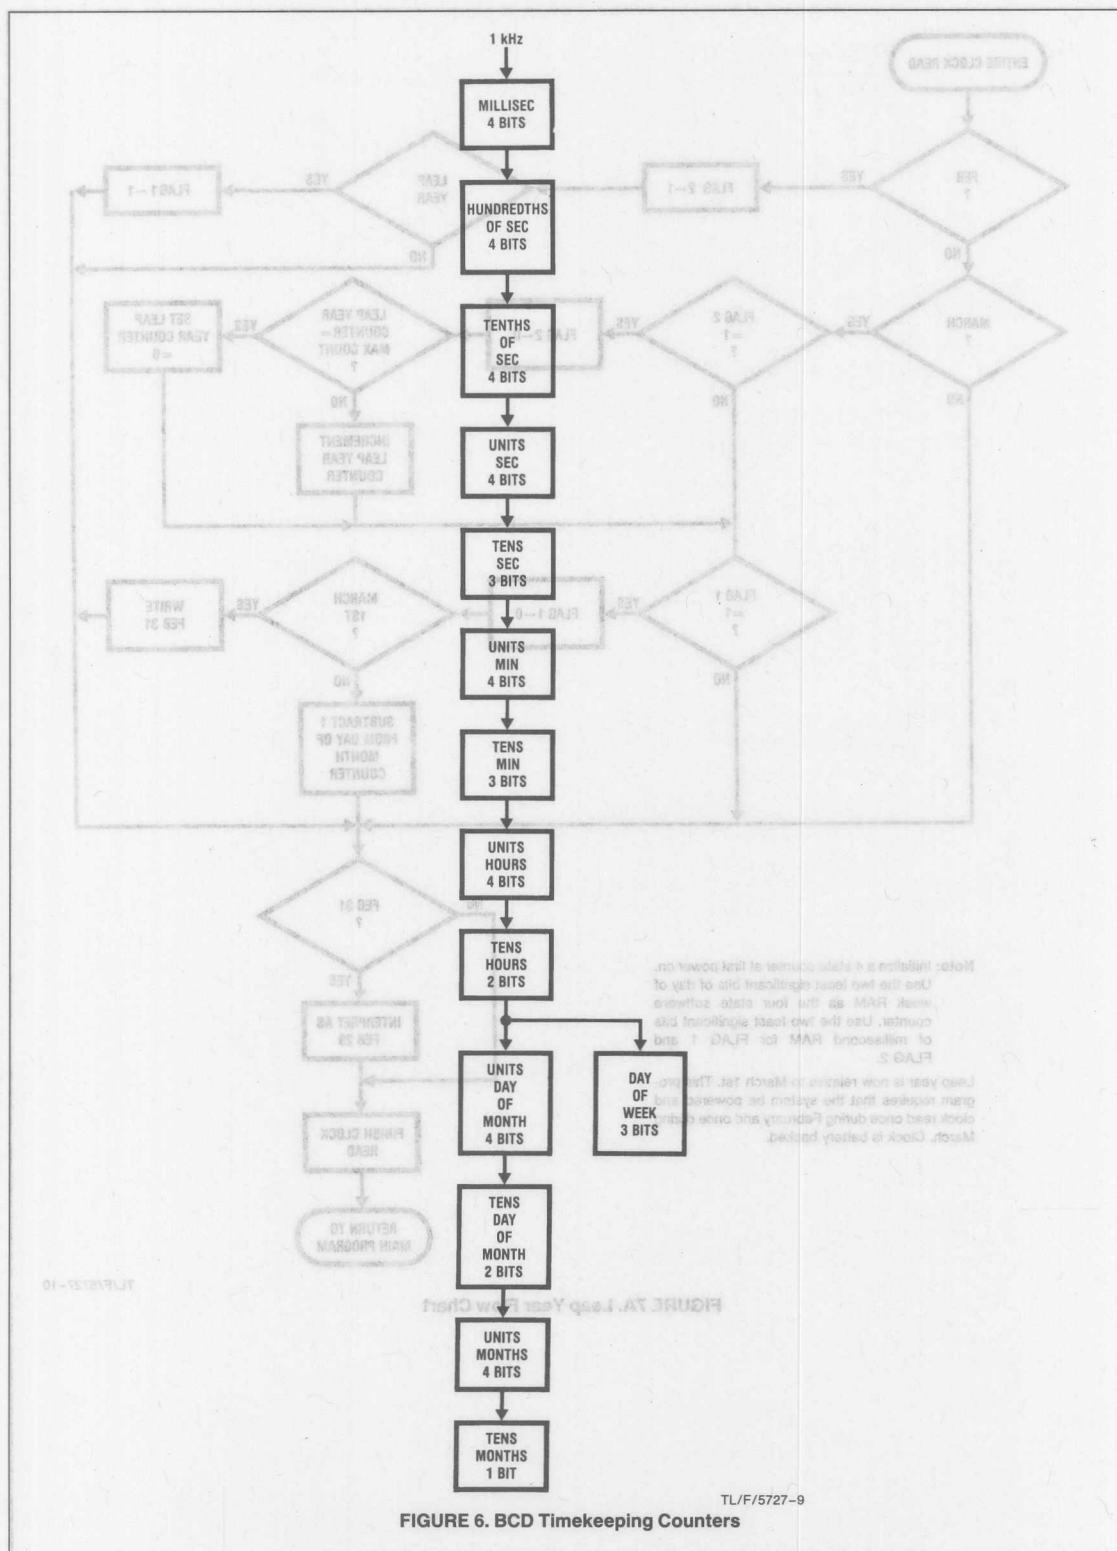

dropping three pulses every 128 counts of the 32,768 Hertz signal. The resulting 32 kHz is then divided to produce 1 kHz which is the internal incrementer for the rest of the timekeeper. This 1 kHz waveform is nonmonotonic with respect to individual periods. As a result, there are 750 short and 250 long periods within a one second interval.

The short period is $1/1024$ seconds, and the long period is $[1/1024 + 3/32768]$ seconds. As a result, the milliseconds, hundredths and tenths of seconds "jitter". The inaccuracy on an individual period basis is about 91 microseconds. The period and number of clock edges are correct over one second within the accuracy of the crystal oscillator. The ten thousandths of seconds counter referred to in the data sheet counts milliseconds. The 1 second and slower signals are jitter free. Refer to Figure 6 for counter block diagram.

TIMEKEEPING COUNTERS

The timekeeping counters are intended to work with valid BCD values. In general, if illegal codes are entered then no guarantee is given for recovery. As shown in Figure 6, the timekeeping stages are arranged as a ripple counter. The month, day of month, and day of week counters count 1 through N. The milliseconds through hours counters count 0 through N. The rollover of a counter stage increments the next higher order counter. This rollover takes place when the highest allowed value plus one is decoded. For example, in a 30-day month, the day of month counter would decode the value 31, reset to one and increment the month counter. If the highest allowed value plus one is written to a counter, the counter will reset when the write is removed and "may" increment the next higher order counter.

For example, if February 29 is written to the clock, the read back will be a "1" in the day of month counter and the month may read "3". However, for leap year use, February 31 may be written. If this is done on Mar 1 at 0 (hours through milliseconds), then the clock will read March 1 after 24 hours. In this way, the value Feb 31 could be used as an indication that the date is really Feb 29. Refer to Figures 7A, 7B, and 7C for flowcharts of a program and alarm interrupt bit map that take leap year into account. Note that the software implemented leap year counter is accurate at least through the year 2048. For a perpetual calendar, a more sophisticated algorithm would be needed.

INTERRUPTS

The MM58167B has two interrupt output pins. The main interrupt (pin 13) is active "high", and is active when the power down pin is "high". When power down (pin 23) is low, the main interrupt output is TRI-STATE. The second interrupt is the "standby interrupt" and is an active low open drain requiring a pull up resistor to VDD. This interrupt is always powered. Refer to *Figure 8* for typical sink current versus voltage out characteristics. Separate control bits exist for the two interrupts. The main interrupt offers two modes of operation which may be combined. Mode 1 is the interactive repetitive interrupt. For this case, a logic 1 is written to one or more bits in the control register (address 11 hex) from D1 through D7, a logic 0 is written into the D0 position. Refer to *Figure 9* for bit configuration of the interrupt control and status registers.

TL/F/5727-12

FIGURE 8. Typical Curve of I vs V of Standby Interrupt

As a result, the clock chip provides an interactive repetitive interrupt, that occurs when the selected counter rolls over. That is, the user must clear the interrupt so the next one can be recognized. This is done by reading the interrupt status register (address 10 hex). This read results in the user obtaining the interrupt status (which interrupt occurred) and

the clearing of the interrupt output as well as the status register. It is the positive-going-edge of the read strobe which causes the preceding. This clearing action precludes polling the status register. For precision timing, the positive-going-edge of the repetitive interrupt should be used as a trigger. The one-per-second through one-per-month repetitive interrupts will be as accurate as the setting of the crystal oscillator. The ten-per-second interrupt will be accurate to about 91 microseconds. Refer to prescaler description for more detail.

The second mode of main interrupt is the "compare" or "alarm". In this case, a specific value is entered in the RAM of the clock. When the time keeping counter(s) match that value, the interrupt becomes active. Refer to *Figure 11* for a typical example. *Figures 9* and *10* show internal interrupt logic and waveforms. In addition to a specific one time interrupt (alarm), a repetitive interrupt can be achieved by reprogramming the selected RAM location with a future event value. The rule of thumb for an "alarm" interrupt is: All nibbles of higher order than specified are set to C hex (always compare). All nibbles lower than specified are set to "zero".

A programming example of the fastest interrupt rate obtainable (500 per second) is given in *Figure 12*. This program written in NSC800™ code (Z80) sets "always compare" conditions (CC hex) in RAM locations 9 through C, E and F. RAM location D which corresponds to the day of the week counter (a single digit), is set to C. RAM location 8 is set to 0. When the first interrupt occurs, the service routine reads the status register and sets the value 2 into RAM location 8. At succeeding interrupts, the values 4, 6, 8 are set into location 8 and the sequence repeats.

If an interrupt is activated and the interrupt occurs during battery backed operation (power down), the main interrupt output will be active high when system power returns.

FIGURE 11. Ram Mapping for Alarm Interrupt at 10:22:00 Every Day

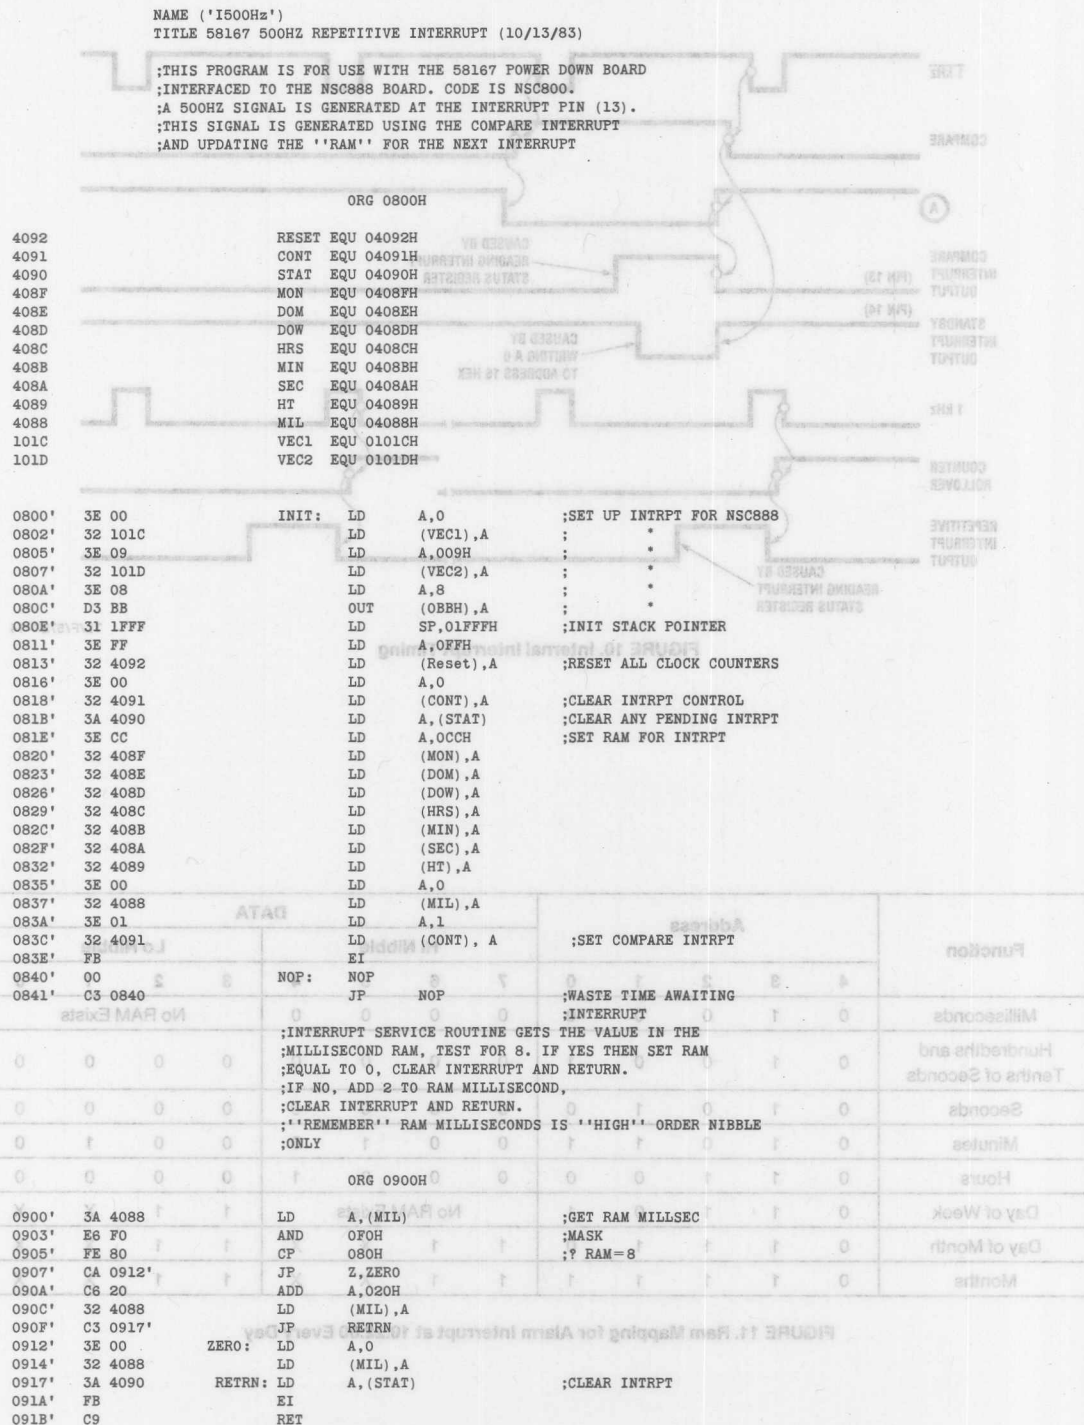

FIGURE 12. NSC800 Assembly Code for 500 Hz Interrupt

STANDBY INTERRUPT

A "1" written to address 16 hex enables the standby interrupt and a "0" disables it. This interrupt also becomes active when a match exists between time keeping counter(s) and a value written into RAM. The standby interrupt can be cleared as soon as it is recognized. The user should ensure that a delay of one millisecond or greater exists prior to reenabling the standby interrupt. This delay is necessary because of the internal signal level which causes the interrupt. If this delay does not occur, then the standby interrupt becomes reactivated until the internal latched compare goes away, which occurs at the next 1 kHz clock. *Figure 10* illustrates interrupt timing.

RAM

RAM is organized as shown in *Figure 2*. There are 4 bits of RAM for each BCD counter. The RAM may be used as general purpose or for an alarm interrupt. It is possible under certain conditions to perform the compare interrupt and use selected bits of the RAM for general purpose storage. Any RAM position that is set for the 'always compare' condition allows the user to manipulate the 2 LO order bits in each nibble. However, the 2 high order bits in each nibble position must be maintained as logic 1's. For example, the user may have an alarm interrupt that does not use the day of the week as a condition for interrupt. Therefore the 2 low order bits might be used as a 4 state software counter to keep track of leap year. Reading and writing the RAM is the same as any standard RAM.

HARDWARE INTERFACE CONSIDERATIONS

There are four basic methods of interfacing the MM58167B to a microprocessor. They are memory mapped, microproc-

essor ports (for single chip microprocessors like the 8048), peripheral adapter, and separate latches. The advantage of memory mapped interface is use of all memory reference instructions. The disadvantages are the processor may need to be "wait-stated" and the environment is noisier with respect to the crystal oscillator. Refer to *Figure 13* for typical bus interface.

Microprocessors that have separate ports (16 are sufficient) offer the capability to interface directly without "wait-stating", or additional device count. Eight of the port bits (data) need to be bidirectional for this interface. *Figure 14* indicates port interface. Programmable peripheral interface devices such as the 8255A or NSC810 afford the user the advantage of timing control by data bit manipulation, as well as a less noisy environment with respect to the oscillator circuit. *Figure 15* depicts the 8255A and NSC810 interface.

External latches may be used in place of the programmable peripheral interface device. This results in higher package count but easier troubleshooting. Also, the latches do not have to be manipulated through a control register. *Figure 16* illustrates the external latch approach. For the peripheral approaches, address, data, chip select, read and write strobes are manipulated by controlling the data bus bits via program execution. The peripheral interface approach facilitates calibration of the oscillator because the chip select, read strobe, and address lines can be set to steady state logic levels. Refer to calibration techniques for more detail.

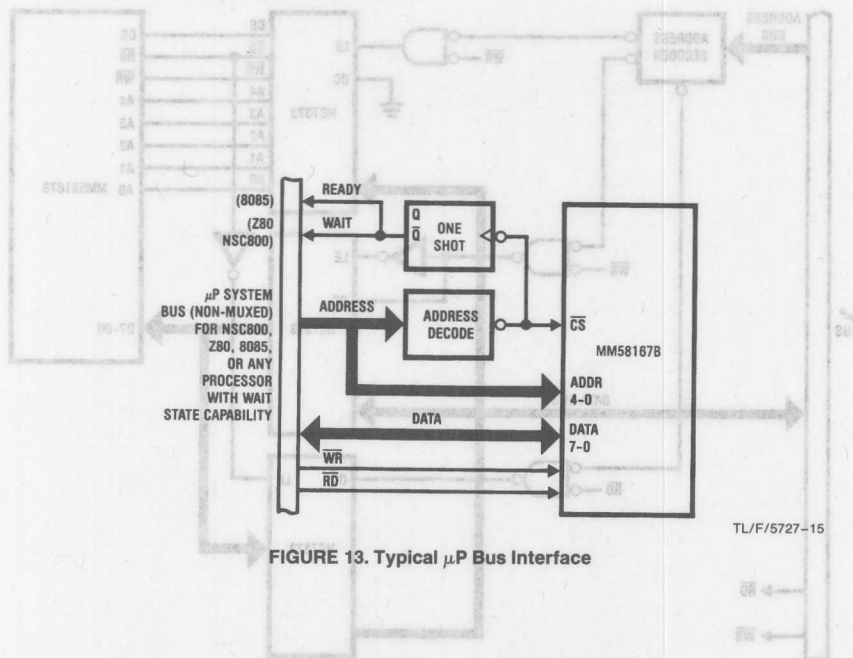

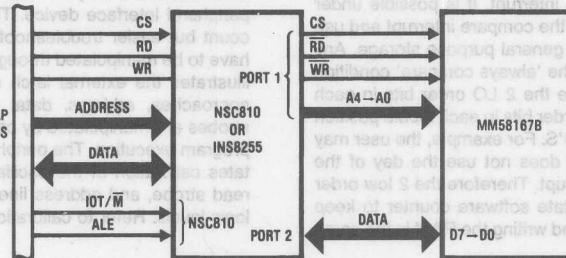

FIGURE 13. Typical μ P Bus Interface

error ports (for single chip microprocessors like the 8048), peripheral register, and separate latches. The advantage of this approach is use of all memory reference signals. The disadvantages are the processor may be "wait-stated," and the environment is noisy with respect to the crystal oscillator. Refer to Figure 13 for pin connections.

External latches may be used in place of the programmable peripheral interface. This results in higher package pin count but no loss of functionality. Also, the latches do not require a control register. For the peripheral interface approach, the user must select, read and write data via the data bus. For the latch approach, the user may select, read and write data via the data bus. The latch approach is preferred because the chip select, read and write signals can be set to steady state. Refer to Figure 14 for pin connections.

POWER DOWN/BATTERY BACKED CONSIDERATIONS

Battery back up of the clock may be considered by the user to maintain time during power failure, provide a "wake-up" alarm, save the time that power failure occurred, calculate how long power failure lasted. The first step in providing a battery backed system is to isolate the system supply from the battery. This is to ensure that the battery is not discharged by the system supply when power failure occurs. Figure 17 shows two techniques to achieve isolation. Figure 17A is implemented using diodes to isolate. In one case a Schottky diode is used to guarantee minimum voltage drop loss, while in the other case an adjustable voltage regulator (LM317) is used from a higher voltage and regulated to about 5.7 volts. A 1N914 diode in series with the regulator achieves the 5 volts for the clock. The Schottky diode has a drop of about 0.3 volts. Thus the V^+ of the clock is typically at 4.7 volts. The user must be cautious about input signals not exceeding the 4.7 volt V^+ , since the clock is a CMOS device. This situation could arise if the devices driving the inputs of the clock were CMOS and received power from the 5 volt system supply. Figure 17B makes use of the low

saturation of a PNP transistor (0.1 volt) to take care of the above situation. The NPN transistor is used to achieve isolation. The zener diode ensures that the circuit stops conducting and appears open circuit before the battery switches in. Some basic considerations must be adhered to in a power down situation where the real time clock is battery backed. One is to ensure no spurious write strobes accompanied by a chip select occur during power down or power up. Another is to guarantee the system is stable when selecting/deselecting the clock. Also, any legitimate write-in-progress should be completed. To accomplish this, hardware is implemented such that early power failure is detected (usually a comparator detects DC failure, a retriggerable one-shot detects AC failure) See Figures 18 and 19. At this point the clock chip is deselected. The worst case is the power fails faster than the detection circuit can cause deselection. When power returns, the hardware detects power on, but the system must be stable before communication is allowed with the real-time-clock.

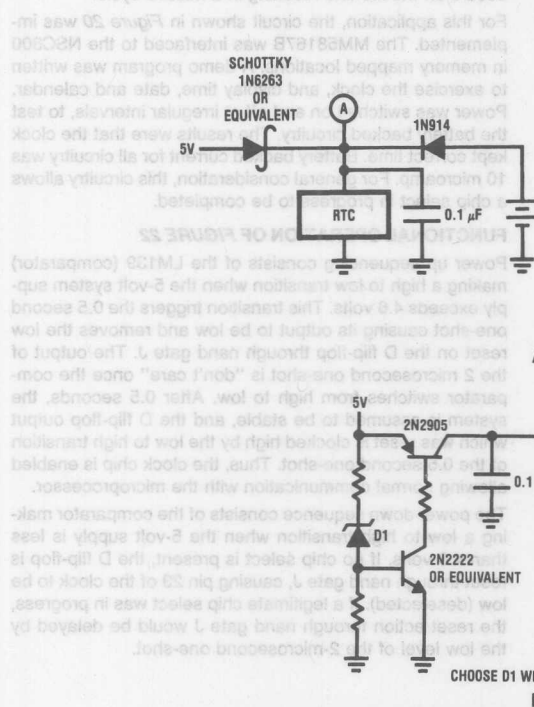

FIGURE 17. Isolating System Supply from Battery

FIGURE 18. Sensing D.C. Failure Using a Comparator

goes low. *Figure 19* shows AC sensing. This technique could cause a spurious deselect of the clock if a "glitch" occurs on the AC line resulting in a missed cycle.

For this application, the circuit shown in *Figure 20* was implemented. The MM58167B was interfaced to the NSC8000 in memory mapped locations. A demo program was written to exercise the clock, and display time, date and calendar. Power was switched on and off at irregular intervals, to test the battery backed circuitry. The results were that the clock kept correct time. Battery backed current for all circuitry was 10 microamp. For general consideration, this circuitry allows a chip select in progress to be completed.

Power up sequencing consists of the LM139 (comparator) making a high to low transition when the 5-volt system supply exceeds 4.6 volts. This transition triggers the 0.5 second one-shot causing its output to be low and removes the low reset on the D flip-flop through nand gate J. The output of the 2 microsecond one-shot is "don't care" once the comparator switches from high to low. After 0.5 seconds, the system is assumed to be stable, and the D flip-flop output which was reset is clocked high by the low to high transition of the 0.5 second one-shot. Thus, the clock chip is enabled allowing normal communication with the microprocessor.

The power down sequence consists of the comparator making a low to high transition when the 5-volt supply is less than 4.6 volts. If no chip select is present, the D flip-flop is reset through nand gate J, causing pin 23 of the clock to be low (deselected). If a legitimate chip select was in progress, the reset action through nand gate J would be delayed by the low level of the 2-microsecond one-shot.

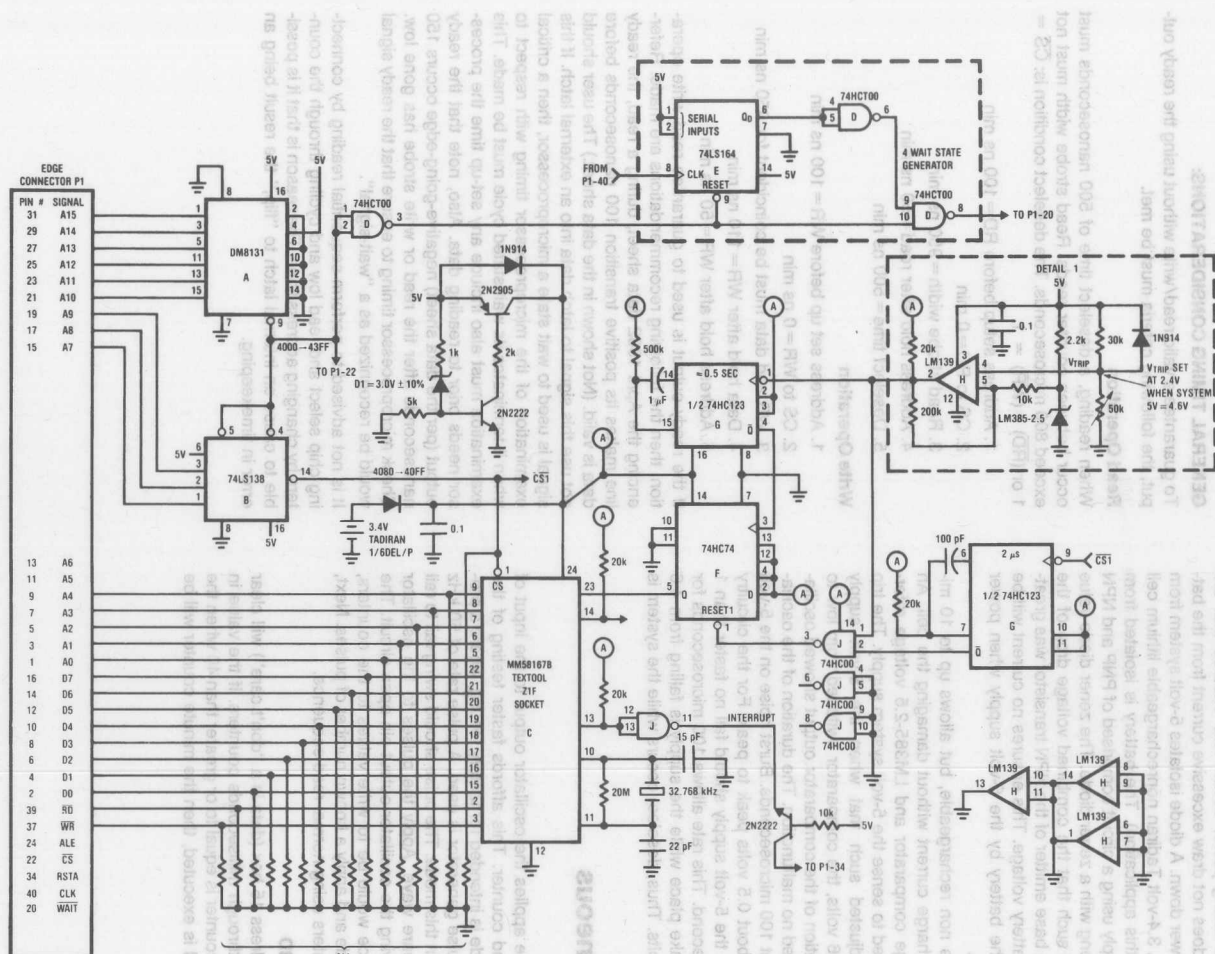

FIGURE 20. Detailed Schematic of Power Down Circuitry, and Interface to NSC888 Board

A wait state generator was implemented using the chip select as the sensing signal. This was necessary to comply with NSC800 wait state timing. The wait generator provides 2 microseconds of access time, which is more than adequate to meet clock chip timing requirements. Pull-down resistors were added to all clock input pins to guarantee no floating inputs during power down. This ensures that the CMOS clock does not draw excessive current from the battery during power down. A diode isolates 5-volt system from the battery (A 3.4-volt Tadiran nonrechargeable lithium cell was used in this application). The battery is isolated from the 5-volt supply using a circuit comprised of PNP and NPN transistors along with a zener diode. The zener diode value was selected such that the combined voltage drop of the zener and the base emitter of the NPN transistor was greater than the battery voltage. This ensures no current will be drawn from the battery by the 5-volt supply when power failure occurs.

The battery is non rechargeable, but allows up to 10 microamps of charge current without damaging the cell. An LM139 voltage comparator and LM385-2.5 voltage reference were used to sense the 5-volt system supply. The trip point was adjusted such that when the 5-volt supply dropped to 4.6 volts, the comparator switched from low to high. Observation of the comparator output showed oscillation, but caused no malfunction. The duration of the oscillation was about 100 microseconds. Burst noise on the 5-volt supply was about 0.5 volts peak to peak. For the circuitry implemented, the 5-volt supply should fall no faster than 1 volt per millisecond. This rate allows 100 microseconds for deselect to take place while the supply is falling from 4.6 volts to 4.5 volts. Thus, deselect occurs while the system is stable.

Miscellaneous

TEST MODE

The test mode applies the oscillator output to the input of the millisecond counter. This affords faster testing of the chip. This mode is intended for factory testing, where a programmable pulse generator is used. A pulse rate of 50 kHz may be used in this mode. The pulse should swing rail to rail and be a square wave. Apply the pulses to the oscillator input pin, leaving the oscillator output pin open circuit. The basic sequence would be to write values to the counters, enter test mode and apply a known number of pulses. Next, read the counters using normal read sequence.

GO COMMAND

A write to address 15 hex (data is a "don't care") will clear the seconds through milliseconds counters. If the value in the seconds counter is equal to or greater than 40 when the GO command is executed, then the minute counter will be incremented.

RESET COMMAND

Writing the value FF hex to address 12 hex causes the hours through milliseconds counters to be reset to zero. The day of week, day of month, and month counters are set to 1. Writing the value FF hex to address 13 hex causes the RAM to be cleared.

GENERAL TIMING CONSIDERATIONS:

To guarantee a valid read/write without using the ready output, the following criteria must be met.

Read Operation

When reading, a deselect time of 500 nanoseconds must occur between counter reads. Read strobe width must not exceed 800 microseconds. The deselect condition is: $\overline{CS} = 1$ or $(\overline{RD}) \cdot (\overline{WR}) = 1$.

1. Address setup before RD = 100 ns min
2. CS to RD = 0 ns min
3. Read strobe width = 950 ns min
4. Address hold after read = 50 ns min
5. Deselect time = 500 ns min

Write Operation

1. Address set up before WR = 100 ns min
2. CS to WR = 0 ns min
3. WR and data must be coincident for 950 ns min
4. Data hold after WR = 110 ns min
5. Address hold after WR = 50 ns min

If the ready output is used to guarantee read/write operation, then the following recommendations are made. Referencing the April 1982 data sheet, during a read, the ready line makes its positive transition 100 nanoseconds before data is valid. (Not shown in the data sheet.) The user should not use this signal to latch data into an external latch. If this signal is used to wait state a microprocessor, then a critical examination of the microprocessor timing with respect to when it terminates its wait state cycle must be made. This examination must also include any set-up time the processor needs prior to reading data. Also, note that the ready output (per the data sheet) negative-going-edge occurs 150 nanoseconds after the read or write strobe has gone low. Check microprocessor timing to ensure that the ready signal would be recognized as a "wait-signal".

It is not advised to perform sequential reading by connecting chip select and read low and cycling through the counters by changing address lines. The reason is that it is possible to cause an internal latch to "flip," the result being an error in timekeeping.

SOFTWARE CONSIDERATIONS

Reading the Counters

A read of one counter plus the rollover status bit or all the counters plus the rollover bit must be done within 800 microseconds. If the rollover status bit is a "1" then a complete read of counter(s) must be performed again. The 800 microsecond value is conservative. If the time between the read of any counter(s) and the rollover status bit exceeds 800 microseconds, then the status bit will always be set. The order of reading must be counter(s) first, then rollover status bit. This is because the positive going edge of the read strobe clears the status bit. Refer to Figure 23. The status bit is enabled for a period of 150 microsecond maximum at a rate of 1 kHz. If during this 150 microsecond period a counter(s) read occurs, the status bit will be set. This is true no matter how often the rollover status is read during that time period. Each rollover status read resets the status bit, but any counter read within the 150 microsecond period will set the rollover status bit. If the counters are read after a repetitive interrupt, then allow 150 microseconds (conservative) from the sense of the interrupt to the read of the counters (ripple delay time) and the data will be valid. If the counters are read after a compare interrupt, the read can occur immediately and will be valid.

Writing the Counters

The counters may be written to in any order, because the write overrides the internal increment. If it is desired to write all the counters without increments occurring in between writes, then the complete write operation must be performed within 800 microseconds. As long as valid BCD values (with respect to the specific counter) are written, no other counter is affected by the write. In general, writing the high order to low order counters is the conservative approach. This method is less susceptible to increments between writes for cases where the writing takes greater than 800 microseconds. For initialization of time, if the "GO" command is issued prior to any write, then 10 milliseconds are available to write from months through tenths and hundredths of seconds without any effect due to internal incrementing.

The MM58174A Real Time Clock in a Battery Backed-Up Design Provides Reliable Clock and Calendar Functions

National Semiconductor
Application Note 359
Steve Munich

INTRODUCTION

National Semiconductor's MM58174A microprocessor real time clock is a reliable and economical solution to adding clock and calendar timekeeping to any system. This metal-gate CMOS circuit (Figure 1) will operate with a supply voltage as low as 2.2V, allowing easy implementation of battery back-up circuitry to maintain timekeeping year after year, even when the system's main supply fails. The MM58174A has counters for months, day of month, day of week, hours, minutes, seconds and tenths of seconds, as well as a register for automatic leap year calculations. Also included are periodic and single interrupt capabilities at 0.5, 5 and 60 second intervals.

This application note will describe how to interface the MM58174A to microprocessors with battery backed-up circuitry. Included will be a functional circuit description, trouble-shooting hints, crystal oscillator adjustment and supplier information. Please refer to the data sheet for AC and DC electrical specifications and timing diagrams.

DESCRIPTION OF FEATURES

Reading and Writing the Time

The MM58174A has BCD counters for tenths of seconds through months, which are accessed by a 4-bit address as

shown in Table I. Months through minutes registers can be read and written to. Tens of seconds, units of seconds and tenths of seconds registers can only be read and are reset to zero when counting is enabled by the start/stop flip-flop. When properly addressed, a nibble of data appears on the data pins DB0-DB3 when a read occurs, and data is accepted on these pins during a write. Any unused data pins will be ignored during a write operation (e.g., days of week uses only DB2 through DB0). To insure proper counter incrementation and accessing, all timing specifications must be observed. It is particularly important that the \overline{RD} strobe width be less than 15 μ s for the highest timekeeping accuracy, but never greater than 15 ms.

Address 13 is a write only leap year status register. Writing a "1" to DB3 at this address will cause the time 02/28 23:59 59.9 to roll over to 02/29 00:00 00.0 in one-tenth of a second. If a "1" is instead written to any other data bit, the roll-over will go to 03/01 00:00 00.0 and the leap year will occur as shown in Table II.

Leap Year-2	0	0	1	0
Leap Year-3	0	0	0	1

Detecting Changed Data

It is possible that during a sequential read of months through tenths of seconds a roll-over may occur. If the time at the start of the read is 23:59 59.5 and it rolls over to the time 00:00 00.0, the microprocessor could read back 23:50 00.00 or 23:00 00.0, etc. Wrong data could also be stored in the clock if the clock is running and is updated during a write (the start/stop flip-flop discussed in the next paragraph will help avoid invalid writes). The MM58174A has a data-changed flip-flop which indicates that a tenths of seconds roll-over has occurred. This flip-flop sets all the data lines high each time the tenths of seconds counter is updated. The "F" on the data lines is then cleared by the next low-to-high transition of any read strobe. In a sequential read of the counters, the tenths of seconds counter may change while the read strobe is low, but an "F" may never be seen before the read strobe comes high. Thus, the "F" may not be detected, although the experimental probability of this occurrence is approximately one in ten thousand reads, in the worst-case. It is essential to restart the whole sequence of reads, beginning from the tens of months register whenever an "F" is encountered on the data lines. A better procedure, outlined in the flowchart of Figure 2, would be to always begin each sequence of reads with the tenths of seconds register and end with this register. If comparing the two values read from this register shows them to be equal, the read is valid. If the compare yields two different values, repeat the same sequence of reads until the same value is read from the tenths of seconds register at the beginning and end of the sequence. It is advisable to use a machine code clock reading routine, or else the time to execute machine-interpreted code may be longer than one-tenth of a second, invalidating all sequential reads.

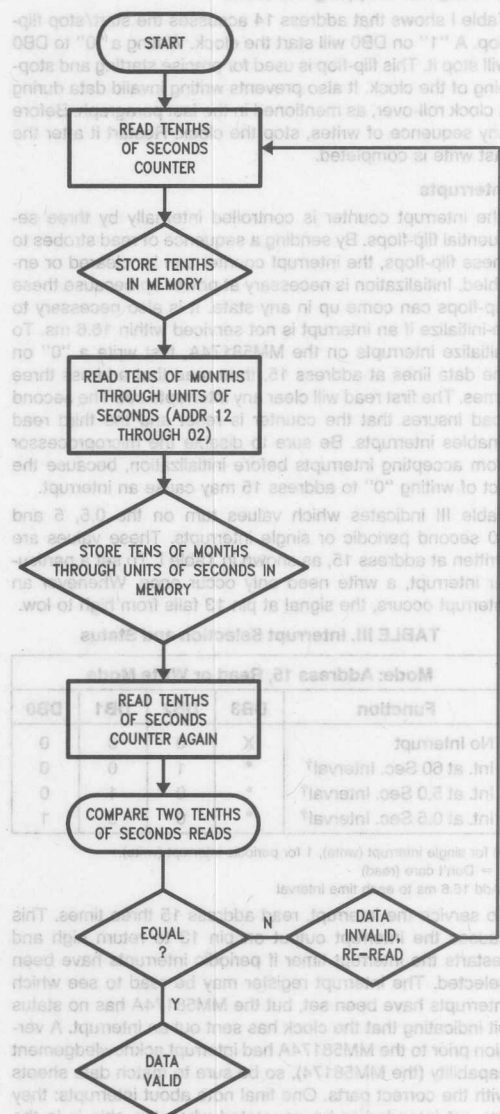

FIGURE 2. Flowchart to Detect Changed Data

Clock Accuracy

Two important factors affect the accuracy of the MM58174A. Any internal counter can jitter by $\pm 30.5 \mu\text{s}$, meaning that the true count can be late by this amount. Also, whenever the clock is restarted (see next section), instead of holding a "0" in the tenths of seconds position for one-tenth of a second, the clock immediately jumps to a "1". So each time the clock is restarted, one-tenth of a second is lost. Accuracy would be maintained if the clock is restarted 0.1 second after the time reference's minutes change.

Starting and Stopping the Clock

Table I shows that address 14 accesses the start/stop flip-flop. A "1" on DB0 will start the clock. Writing a "0" to DB0 will stop it. This flip-flop is used for precise starting and stopping of the clock. It also prevents writing invalid data during a clock roll-over, as mentioned in the last paragraph. Before any sequence of writes, stop the clock. Restart it after the last write is completed.

Interrupts

The interrupt counter is controlled internally by three sequential flip-flops. By sending a sequence of read strobes to these flip-flops, the interrupt counter can be cleared or enabled. Initialization is necessary at power-up because these flip-flops can come up in any state. It is also necessary to re-initialize if an interrupt is not serviced within 16.6 ms. To initialize interrupts on the MM58174A, first write a "0" on the data lines at address 15, then read that address three times. The first read will clear any interrupts set. The second read insures that the counter is reset and the third read enables interrupts. Be sure to disable the microprocessor from accepting interrupts before initialization, because the act of writing "0" to address 15 may cause an interrupt.

Table III indicates which values turn on the 0.5, 5 and 60 second periodic or single interrupts. These values are written at address 15, as shown in Table I. To set a particular interrupt, a write need only occur once. Whenever an interrupt occurs, the signal at pin 13 falls from high to low.

TABLE III. Interrupt Selection and Status

Mode: Address 15, Read or Write Mode				
Function	DB3	DB2	DB1	DB0
No Interrupt	X	0	0	0

*0 for single interrupt (write), 1 for periodic interrupt (write).

X = Don't care (read)

†Add 16.6 ms to each time interval

To service the interrupt, read address 15 three times. This causes the interrupt output on pin 13 to return high and restarts the interrupt timer if periodic interrupts have been selected. The interrupt register may be read to see which interrupts have been set, but the MM58174A has no status bit indicating that the clock has sent out an interrupt. A version prior to the MM58174A had interrupt acknowledgement capability (the MM58174), so be sure to match data sheets with the correct parts. One final note about interrupts: they are not intended to be generated when the chip is in the sleep mode (see next paragraph). The MM58174A must be running with at least a 4V supply for interrupts to function.

Powering Down and Up

When the supply to pin 16 falls below 5V, timing becomes much more critical because propagation delays increase with a lowering of the power supply voltage. Note that the data sheet has timing specifications for 5V, and although

the part is fully operational down to 4V, your design may not tolerate it. When the supply falls below 4V but stays above 2.2V, the MM58174A is in the sleep mode and only microamps are drawn from the battery. In this mode, the chip is not accessible by reading or writing, but time is being maintained.

On power-up from zero volts V_{CC} , one must make sure the chip is not in the test mode. This is done by writing a "0" to DB3 at address 0. It is advisable to do this even when coming out of the sleep mode. The test mode is mainly for production testing of the circuit.

There are several things to consider when designing the power-down circuitry. The basic functional requirements are to disable the chips before full power loss or malfunction, and to wait for V_{CC} to stabilize before enabling the chip on power-up. A desirable feature would be to allow the read or write in progress to complete. Figures 3 and 4 include a typical power-down circuit which achieves these goals. In general, avoid using TTL since it is not rated below 4.5V. The power-down circuitry's signals to the MM58174A must not be allowed to deviate more than a diode drop above the clock's supply or below ground in order to avoid triggering SCR latch-up. Finally, be sure to use a PNP switch instead of a diode to disconnect the power supply from the battery. This will allow the MM58174A to see a V_{CC} closer to 5.0V coming from the main supply rather than 4.3V, enhancing timing requirements. See Figures 3 and 4 and the next section for more information on design of power-down circuitry.

DESIGN IDEAS

Figures 3 and 4 show two possible ways of interfacing the MM58174A to a microprocessor; the former with wait states and the latter eliminating wait states using the NSC810A RAM/IO timer as a peripheral interference adapter.

Real Time Clock Interface with Wait States

The design of Figure 3 uses wait states to guarantee that the set-up and hold times of the MM58174A are satisfied. If one can afford to constrict his microprocessor throughput while accessing the MM58174A, this design has the advantages of simplified software and somewhat less expensive hardware. Decreased microprocessor throughput is usually not a consideration in most applications unless the clock is continuously being accessed for a real time display, while at the same time the processor is multiplexing the execution of other tasks.

The HC688s of Figure 3 are used to fully decode the 4 bits of address space for the real time clock and to generate chip select and wait states. Each time an address between 4080H and 408FH appears on the address lines of the bus, the second of the cascaded HC688s generates a low strobe that allows the power-down circuitry to create a chip select, and also fires an HC123 one-shot configured to drive a 2 μ s wait state onto the wait line of the microprocessor bus. For wait lines of the opposite polarity, the HC123's Q output could be used. A shift register may also be configured to give the proper access time delay.

AN-359

Power is supplied to the parts from a 5.0V supply which is disconnectable by a PNP switch to a battery. When the main supply is on, the PNP in saturation brings the voltage at node B to about 4.8V. The diode near node B is back-biased to keep the battery from discharging and to protect it from damage by isolating it from 5V. If the main supply were to drift far enough downward, the diode would forward-bias, bringing node B to 0.7V below the battery voltage. Since the clock is now in the sleep mode, the only parts needed to be powered by the battery are the clock and the power-down circuitry. An NPN between the bus connection and the WR pin, as shown *Figure 3*, will reduce power consumption without inverting the signal into this pin. This is made necessary because both CS and WR pins on the MM58174A have internal pull-ups to V_{CC} which cause unnecessary current drain if either input were to become grounded. The NPN switch isolates the WR from ground, while the CS input is held high by the power-down circuitry.

Power-Down Circuitry Operation

The power-down circuitry of *Figures 3* and *4* consists of seven HC00 NAND gates and an LM139 low voltage comparator with an assortment of resistors, diodes and capacitors at the differential input.

With the 5.0V supply on, the assortment of diodes, resistors and capacitors at the comparator's differential input creates a low output. But when the supply is off, the battery pulls this output high through the 20 k Ω resistor. On power-up, after a short delay by the diodes and capacitors at the inverting input, the LM139's low level output enables a latch made from HC00 NAND gates to allow a chip select from the 'HC688 (*Figure 3*) or the NSC810A (*Figure 4*) to flow through to pin 1 (CS) of the MM58174A.

As power from the 5.0V supply falls below 4.5V, the comparator's output immediately goes high. This threshold voltage is adjustable by the 200 k Ω potentiometer at the LM139's inverting input. A high output from the comparator to the NAND latch will disable chip selects to the MM58174A.

So as power begins to fail, this circuit will allow reads or writes to the MM58174A to go to completion if the chip is selected before the LM139's output goes high. It is assumed that the MM58174A's CS pin returns high before the supply falls to 4.0V (the minimum V_{CC} to access the chip). The length of the chip select strobe determines the limit of how fast the main power supply can drop from 4.5V to 4.0V. In situations where power failure detection is more critical, it is suggested that the comparator's output be connected to the microprocessor's highest priority interrupt so that the necessary software can be accessed.

This power-down circuitry has the advantage of proper operation in the presence of noise. With a slowly falling power supply in a noisy environment, the comparator's output may oscillate momentarily. This oscillation will have no bearing on the chip select signal to the MM58174A in this circuit because the HC00 latch only allows chip selects when the LM139 output is high, and it also does not alter their length once they begin. When the supply falls low enough to stop the comparator from oscillating, chip selects are locked out. One may consider the time that the comparator bounces as a delay before chip access is completely locked out as the standby mode is entered. If the cessation of comparator oscillation is desired, hysteresis can be added. A diagram of this can be found in the LM139 data sheet.

Real Time Clock Interface without Wait States Using a PIA

Figure 4 shows the details of a design using the NSC800™ CMOS microprocessor and the NSC810A peripheral interface adapter. This design has the advantages of lower chip count and the absence of wait states. Similar PIAs, such as the INS8255 or the 8155, could be used with some software adaptation. The power-down circuitry is operationally equivalent to that of *Figure 3*, except that in this design the chip select is created by the PIA. Only the essential connections between the NSC800 and the NSC810A are shown in *Figure 4*.

The NSC800 is an 8-bit CMOS microprocessor combining the features of the Intel 8085 and the Zilog Z80®. In this application 8085 code is used to manipulate the control strobes and handle interrupts as detailed in *Figures 5* through *9*. The interconnection between the NSC800 and the NSC810A is straightforward, except for the CE connection on the NSC810A. By tying CE to A13 of the NSC800, chip enabling occurs whenever an IN 2X or an OUT 2X instruction is executed, because the same port address appears on NSC800 lines AD0-AD7 as on A8-A16. Using 2X will raise A13 on the NSC800 high, where X represents a specific port address. This method of enabling is entirely optional. For more information on the NSC800 and NSC810A, refer to the NSC800 Microprocessor Family Handbook.

Software Description

The ports on the NSC810A are specially configured to control the data, address and control lines. The software allows the port signals to fulfill timing requirements. Port C is used to control the WR, RD and CS lines, port B is used to control the address lines, and port A is used to read and write the data.

The NSC810A is configured into the strobed input mode in the read subroutine in order to get the shortest possible RD strobe. As stated previously, the read strobe must be under 15 μ s to guarantee proper counter operation. The RD strobe is fed back to the PC2/STB input of the NSC810A in order to latch in the data from the MM58174A. The read subroutine of *Figure 5* begins by setting the port C direction. All bits are set for output, except PC2/STB, which is set for input. Port B is set out and port A is set in. Next, all the control strobes from port C are set high using bit set. Before calling the read routine, the MM58174A address to be accessed was loaded into the NSC800's register B, and it is now sent out on port B. Bit clear is used to lower the CS strobe from PC5. The mode definition register is then written to for selecting the strobed mode of the NSC810A. Bit clear is used to lower the RD strobe from port C, and before it is raised again, a MOV instruction puts control values from port C into the accumulator in the shortest time possible. Using these three instructions, the read strobe is held low for about 5 μ s. The rising edge of the RD strobe is fed into PC2/STB to latch the data into port A, and the IN instruction reads the data. Before exiting the read subroutine, the mode definition register of the NSC810A is again accessed to return the PIA's operation to the basic I/O mode. A wait loop may be added to the read subroutine or elsewhere in the code to limit the number of read strobes to less than 10,000 per second. This specification has been added because

strokes. However, there is no need to latch the data in port A, so the basic I/O mode is used. The write subroutine uses the control strokes from port C by beginning with all three strokes high, manipulating CS and WR low, and finally bringing these port outputs high again. Before calling the write subroutine, the desired address to be accessed is to be stored in the NSC800's register B, and data stored in register A.

FIGURE 6. Write Subroutine

that a DI instruction is used to disable interrupts before a "0" is written to address 15. Also included is the code to initialize interrupts on the MM58174A. Figure 8 shows the interrupt service routine, while Figure 9 shows a method of time setting by first stopping the clock, then restarting it once the setting is complete.

powered by the battery are in the MM58174A have an NPN between the bus connection and the WR pin, as shown in Figure 3, will reduce power consumption without inverting the signal into this pin. This is made necessary because both CS and WR pins on the MM58174A have internal pull-ups to VCC which cause unnecessary current drain if either input were to become grounded. The NPN switch isolates the WR from ground while the CS input is held high by the power-down circuitry.

Power-Down Circuitry Operation

The power-down circuitry of Figure 3 and 4 consists of seven HC00 NAND gates and an LM139 low voltage comparator with an assortment of resistors, diodes and capacitors at the differential input.

With the 5.0V supply on the assortment of diodes, resistors and capacitors at the comparator's differential input creates a low output. But when the supply is off, the battery pulls this output high through the 50 kΩ resistor. On power-up, after a short delay by the diodes and capacitors at the varying input, the LM139's low level output enables a latch made from HC00 NAND gates to allow a chip select from the 'H088 (Figure 3) or the NSC800 (Figure 4) to flow through to pin 1 (CS) of the MM58174A.

As power from the 5.0V supply falls below 4.5V, the comparator's output immediately goes high. This threshold voltage is adjustable by the 200 kΩ potentiometer at the LM139's inverting input. A high output from the comparator to the NAND latch will enable chip select to the MM58174A.

So as power begins to fall, this circuit will allow the MM58174A to go to completion if the chip select is selected before the LM139's output goes high. It is assumed that the MM58174A's CS pin return high before the supply falls to 4.0V, the minimum VCC to access the chip. The length of the chip select stroke determines the time how fast the main power supply can drop from 4.5V to 4.0V. In situations where power failure detection is more critical, it is suggested that the comparator's output be connected to the microprocessor's highest priority interrupt so that the necessary software can be accessed.

This power-down circuitry has the advantage of proper operation in the presence of noise. With a slowly falling power supply in a noisy environment, the comparator's output may oscillate momentarily. This oscillation will have no bearing on the chip select signal to the MM58174A in this circuit because the HC00 latch only allows chip select when the LM139 output is high, and it also does not alter their length once they begin. When the supply falls low enough to stop the comparator from oscillating, chip select is locked out. One may consider the time that the comparator produces as a delay before chip access is completely locked out as the standby mode is entered. If the cessation of comparator oscillation is desired, hysteresis can be added. A delay line can be found in the LM139 data sheet.

Crystal information

Choose one of the following crystal types: parallel resonant or tuning fork (NT CUT or XY BAR) with a Q > 35,000 and a frequency of 32.768 KHz. The load capacitance required is 50 pF. The choice of crystal accuracy and temper-ature coefficient are left to the user. Two crystals used in our lab are RCD's RV-38 and Sanyo's NTF3238C.

FIGURE 7. Initialization

FIGURE 9. Recommended Procedure for Setting Time

FIGURE 10. Crystal

Oscillator Design

The MM58174A is driven by a standard Pierce oscillator. Figure 10 shows both the internal and external component sizes to be used. For crystals with a power rating of less than 1 μ W, a 200 k Ω resistor, in series with the oscillator output, should be used to insure that the crystal is not over-driven. The typical gain for the internal inverter and internal 200 k Ω series resistor is 20 at 1 kHz input frequency and about 5 at 30 kHz. The oscillator may take from two to seven seconds to begin oscillating due to the high Q of the crystal.

Crystal Information

Choose one of the following crystal types: parallel resonant or tuning fork (NT CUT or XY BAR) with a Q > 35,000 and a frequency of 32,768 kHz. The load capacitance required ranges from 9 pF to 13 pF. The maximum power rating is 20 μ W. The choice of crystal accuracy and temperature coefficient are left to the user. Two crystals used in our lab are RCD's #RV-38 and Saronix's #NTF3238C.

FIGURE 10. Crystal Oscillator

TL/F/6169-5

Oscillator Adjustment and External Drive

A well-tuned oscillator for the MM58174A will have a frequency error of no more than ± 10 ppm. This would result in the clock being off by ± 5 minutes per year. This is a worst-case number, taking into account such factors as temperature variation (-40°C to $+85^{\circ}\text{C}$) and supply variation (2.2V to 5.5V). The external oscillator components can also contribute to error and this should be taken into account by the user.

Adjusting the trimmer capacitor at pin 15 will minimize the oscillator error. But simply putting a scope probe on the crystal will load the oscillator with at least 10 pF, significantly altering the frequency. There are two good ways of isolating the probe from the oscillator. One method is to put the part in the test mode by writing a "0" to DB3 at AD0, then tune the signal at DB0 to 16,384.00 Hz using an accurate frequency counter. Another method would be to isolate the oscillator from the probe by adding an inverter to the small capacitance at pin 14. This would load the oscillator, but the input capacitance of the gate would not be affected by a probe at the output. The total capacitance on pin 14 should be kept near 15 pF.

To drive the oscillator from an external clock, connect the clock to pin 14 (crystal out) and tie pin 15 (crystal in) high.

CONCLUSION

The MM58174A can easily be interfaced to a microprocessor to bring the functions of a real time clock and calendar to any system. With a power-fail/back-up circuit, the system will be able to keep accurate time for years, independent of the system power supply.

The MM58274C Adds Reliable Real-Time Keeping to Any Microprocessor System

National Semiconductor
Application Note 365
Peter K. Thomson

AN-365

INTRODUCTION

When a Real-Time Clock (RTC) is to be added into a digital system, the designer will face a number of design constraints and problems that do not usually occur in normal systems. Attention to detail in both hardware and software design is necessary to ensure that a reliable and trouble free product is implemented.

The extra circuitry required for an RTC falls into three main groups: a precise oscillator to control real-time counting; a backup power source to maintain time-keeping when the main system power is removed; power failure detection and write protection circuitry. The MM58274C in common with most RTC devices uses an on-chip oscillator circuit and an external watch crystal (frequency 32.768 kHz) as the time reference. A battery is the usual source of backup power, along with circuitry to isolate the battery-backed clock from the rest of the system. Like any CMOS component, the RTC must be protected against data corruption when the main system power fails; a problem that is very often not fully appreciated.

Rather than dealing strictly with any one particular application, this applications note discusses all of the aspects involved in adding a reliable RTC function to a microprocessor system, with descriptions of suitable circuitry to achieve this. Hardware problems, component selection, and physical board layout are examined. The software examples given in the data sheet are explained and clarified, and some other software suggestions are presented. Finally a number of otherwise unrelated topics are lumped together under "Miscellany"; including a discussion on how the MM58274C may be used directly to upgrade an existing MM58174A installation.

1.0 HARDWARE

Selecting the correct components for the job and implementing a good board layout is crucial to developing an accurate and reliable Real-Time Clock function. The range of component choices available is large and the suitability of different types depends on the demands of the system.

1.1 COMPONENT SELECTION

With reference to *Figure 1*, the oscillator components and the battery are examined and the suitability of different types is discussed.

work with a standard low power of 32.768 kHz frequency. The d is shown complete in *Figure* s the oscillator into its linear start-up. The 200 k Ω resistor er from overdriving the crystal. used (i.e., less than 1 μ W) an 0 k Ω may have to be added to

The oscillator will drive most normal watch crystals, with up to 20 μ W drive available from the on-chip oscillator.

1.1.2 Loading Capacitors

1.1.3 Backup Battery

CHANGING THE WORLD

Capacitors

When the system is permanently powered, and any long term removal of system power (i.e., more than a few hours) requires complete restarting, then a 1–2 Farad capacitor may be sufficient to run the clock during the power down. This can keep the clock running for 48–72 hours.

Nickel-Cadmium Cells

Nickel-cadmium (Ni-Cad) cells can be trickle-charged from the system power supply using a resistor as shown in Figure 7. The exact value of resistor used depends on the capacity and number of cells in the battery. Consult the manufacturers data for information on charging rates and times.

A 3- or 4-cell battery should be used to power the clock (the nominal battery voltages are 3.6V for 3 cells in series and 4.8V for 4 cells), with 3 cells preferable. PCB mounting batteries of 100 mAh capacity are available and these will give around 6 months data retention (at normal room temperature). For this cell type to be used the system must spend a large proportion of its time turned on to keep the battery charged (i.e., used daily).

Alkaline

Alkaline cells are among the least expensive primary cells which are suitable for use in real-time clock applications. They are available in a large range of capacities and shapes and have a very good storage (shelf) life.

Two cells in series will provide a nominal 3V, which is adequate to power the clock (via the isolating diode). The main problem with the alkaline system is that the cell terminal voltage drops slowly over the life of the cell. When the voltage at the clock supply pin drops to 2.2V, the cells must be replaced (battery voltage around 2.6V–2.7V). With present alkaline cells, this point is usually reached when the cells are only $\frac{1}{2}$ to $\frac{2}{3}$ discharged.

Provisions must be made either to check the battery voltage at regular intervals or to replace the cells regularly enough to avoid the danger of using discharged cells. Once again the manufacturers data regarding capacity and cell voltage against time must be examined to determine a suitable cell selection. A good alkaline system will supply 1–2 years continuous time-keeping.

Lithium

Lithium cells are the most suitable for real-time clock applications. A single cell with 3V potential is sufficient to power the system. The cell potential is very stable over use and the storage life is excellent. The energy density of lithium cells is very high, giving enough capacity in a physically small cell to power the clock continuously for at least 5 years (at room temperature using a 1,000 mAh cell).

Several cells which are recommended for RTC use are D2/3A*, D2A*, and 1/6DEL/P*. Each have 1,000 mAh capacity. These cells are available with solder pin connections for PCB mounting, giving a reliable backup supply.

Other Cells and Notes

There are many other types of cells, both primary and secondary, which may be adapted for RTC use. When selecting a cell type, attention must be paid to:

- Cell capacity and physical size.
- Storage (shelf) life.
- Voltage variation over use.
- Operating temperature range.
- The method of battery connection and mounting.

In general, soldered cells are preferable to connector mounted cells. With replaceable batteries, the battery and connector contacts must be kept thoroughly clean. Dirty or corroded contacts can cause the clock to be starved of power, giving erratic and unreliable performance. The ease of operator access for cell replacement should also be considered.

Temperature Range

The performance of any cell will be satisfactory for most office or domestic environments. When "ruggedized" equipment is to be used (i.e., field portable equipment, automotive, etc.) the temperature specification of different cell types should be taken into account when selecting a cell. Lithium cells offer good performance over 0°C–70°C with little loss in capacity. Once again, the manufacturer's data should be examined to determine suitability, especially since different cells of the same type can have markedly different characteristics.

Few types of cells will offer any useful capacity at temperatures in or below the range 0°C–10°C, and fewer still will operate over the full military temperature range (–55°C to +125°C). Solid lithium cells and mercury-cadmium cells are two systems which can cover this range.

1.2 BOARD LAYOUT

1.2.1 Oscillator Connection

The oscillator components must be built as close to the pins of the clock chip as is physically possible. The ideal configuration is shown in Figure 4. From Figure 2, the oscillator circuit, it can be seen that both Osc In and Osc Out are high impedance nodes, susceptible to noise coupling from adjacent lines. Hence the oscillator should, as far as is practicable, be surrounded by a guard ground. The absolute maximum length of PCB tracking on either pin is 2.5 cm (1 inch). Longer tracks increase the parasitic track to track capacitances, increasing the risk of noise coupling and hence reducing the overall oscillator stability.

Where the system operates in humid or very cold environments (below 5°C), condensation or ice may form on the PCB. This has the effect of adding parasitic resistances and capacitances between pins 14 and 15, and also to ground. This variation in loading adversely affects the stability of the oscillator and in extreme cases may cause the oscillator to stop.

*Duracell Trade Number.
**Tadiran Trade Number.

Keeping the PCB tracks as short as possible will help to minimize the problem, and on its own this may be sufficient. Where the operating conditions are particularly severe, the PCB and oscillator components should be coated with a suitable water repellent material, such as lacquer or silicon grease (suitability being determined by the electrical properties of the materials—high impedance and low dielectric constant).

Figures 2 and 4 show the trimmer placed on Osc Out. The placement of the trimmer capacitor on either Osc In or Osc Out is not critical. Placing the trimmer on Osc Out yields a smaller trim range, but less susceptibility to changes in trimmer capacitance. Placement of the trimmer capacitor on Osc In gives a wider trim span, but slightly greater susceptibility to capacitance changes.

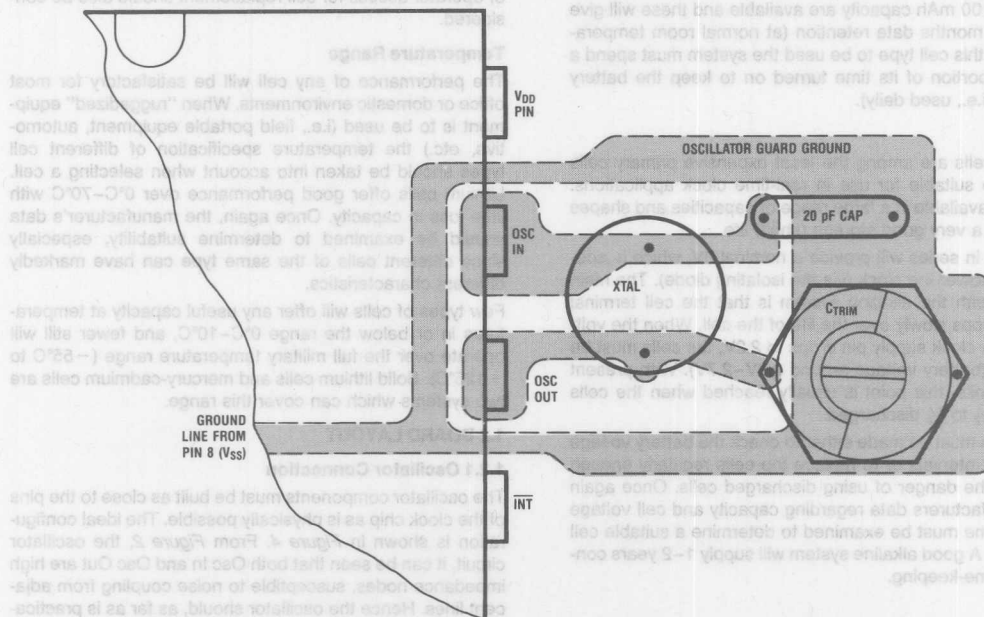

FIGURE 4. Oscillator Board Layout

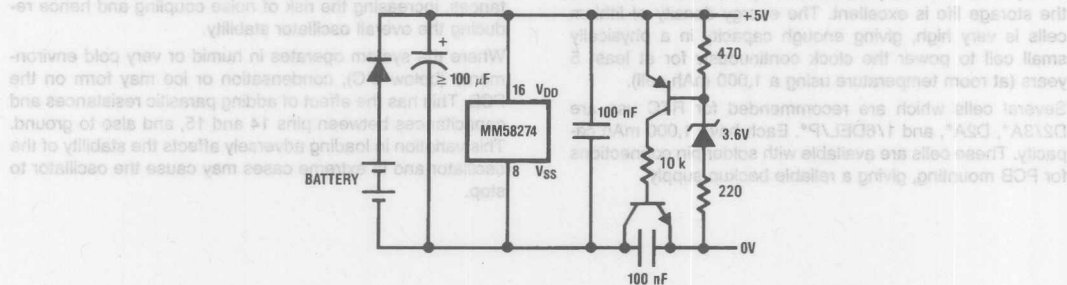

FIGURE 5. Simplified Power Supply Diagram with 100 μ F Capacitor Added

1.2.2 Battery Placement

For the battery, placement is less critical than with the oscillator components. Practical considerations are of greater importance now; i.e., accessibility. The battery should be placed where it is unlikely to be accidentally shorted or disconnected during routine operation and servicing of the equipment.

When replaceable cells are used, connecting a 100 μ F capacitor across the RTC supply lines will keep the clock operating for 30–40 seconds with the battery disconnected (Figure 5). This allows the battery to be replaced regardless of whether or not the main supply is active.

1.2.3 Other Components

The placement of the other RTC dedicated components (e.g., supply disconnection and power failure protection components) is not particularly critical. However, the same guidelines as applied to the battery should be followed when the PCB layout is designed.

1.3 POWER SUPPLY ISOLATION SCHEMES

1.3.1 The Need for Isolation

There are two reasons for disconnecting the clock circuit from the rest of the system:

1. To prevent the backup battery from trying to power the whole system when the main power fails.
2. To minimize the battery current (and extend battery life) by preventing current leakage out of the RTC input pins.

The MM58274C inputs have internal pull-up devices which pull the inputs to V_{DD} in power down mode. This turns off the internal TTL input buffers and causes the μP interface functions of the clock to go to full CMOS logic levels, drawing no supply current (except for the unavoidable leakage current of the internal MOS transistors). For the MM58274C this is achieved by isolating the ground (V_{SS}) supply line from the rest of the system.

Figures 6a and 6b show the two cases where first V_{DD} (6a) and then V_{SS} (6b) are open-circuited. The line out from the MM58274C represents any of the Control, Address, or Data lines on the RTC, with the internal pull-up resistor shown. The two diodes and resistor R_S represent the logic device connected to the RTC input and the resistance of the rest of the system with no power applied.

When V_{DD} is open-circuited as in Figure 6a, there is a complete current path, shown by the arrows, out of the RTC input and through the external circuitry. This battery current

FIGURE 6. Current Leakage Prevention by Proper Supply Disconnection

is a complete waste and serves only to reduce the cell life. Depending on the value of R_S , the voltage level at the pin may fall low enough to turn on the internal TTL level buffer, wasting further current as the buffer is no longer fully CMOS.

With V_{SS} disconnected (Figure 6b), there is no return path to the battery and the pin is pulled completely up to V_{DD} . The TTL buffer is switched off and no power is lost.

1.3.2 Isolation Techniques I—5V Supply Only

Figure 7 shows the isolation circuit suggested in the MM58274C data sheet. This circuit provides complete disconnection where only the system +5V is available for switching control.

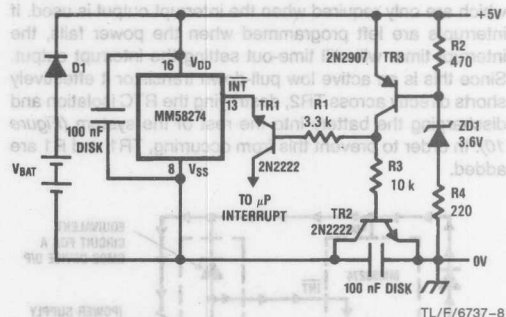

FIGURE 7. 5V Isolation Circuit

TR2 is the disconnecting device, which is controlled by TR3 and its associated circuitry. TR3 is turned on by its bias chain R2, ZD1, R4 as the system supply rises up to 4.2V. TR3 and R3 then turn on TR2 to connect the clock to the system supply. D1 isolates the backup battery when the system supply is active. The 100 nF disk capacitors decouple the supply during R/W operations and should be included in any disconnection scheme.

TR3 is necessary to prevent R3 and TR2 from leaking battery current in the power down condition. The circuit without TR3 is shown in Figure 8 where TR2 has been replaced by equivalent diodes to clearly show the problem. The circuitry could be simplified by replacing TR3 with a Zener diode (Figure 9). There will be a small loss of current down through TR2 however, as the Zener will pass a small leakage current at below its "knee" voltage. Thus the Zener should be selected for its low current capability.

R_S = System Resistance with No Power Applied

FIGURE 8. Current Leakage in Simplified Disconnection Schemes

TL/F/6737-10
FIGURE 9. Alternative Supply Disconnection Scheme Sensing 5V (Decoupling Capacitors Omitted for Clarity)

Finally TR1 and R1 (Figure 7) are optional components which are only required when the interrupt output is used. If interrupts are left programmed when the power fails, the interrupt timer will still time-out setting the interrupt output. Since this is an active low pull-down transistor it effectively shorts directly across TR2, destroying the RTC isolation and discharging the battery into the rest of the system (Figure 10). In order to prevent this from occurring, TR1 and R1 are added.

TL/F/6737-11
FIGURE 10. Battery Discharge Path via Unisolated Interrupt Output

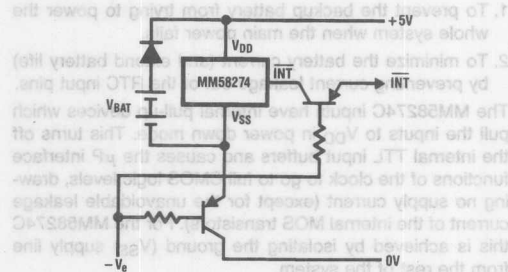

None of the disconnection components are at all critical, with general purpose transistors being completely adequate for the task. D1 should be a small-signal silicon or germanium diode.

Equivalent circuit for a CMOS device O/P (POWER SUPPLY EQUIVALENT POWERED DOWN SOURCE RESISTANCE)

1.3.3 Isolation Techniques II—Negative Supply Switched

Where a negative voltage supply is available (either regulated or unregulated) the circuit of Figure 11 may be used. This is similar in operation to its diode equivalent shown in Figure 12, where the voltage drops across the diodes provide the correct potential to the clock. Figure 11 has the advantage, however, that the clock power is supplied from the ground line by transistor action, rather than via the resistor as in Figure 12. Less power is dissipated in the resistor as only transistor bias current need be drawn.

TL/F/6737-12
FIGURE 11. Negative Voltage Driven Supply Disconnection Scheme (Decoupling Capacitors Omitted for Clarity)

TL/F/6737-13
FIGURE 12. Diode Equivalent Circuit of Figure 11

1.3.4 Other Methods

There are many other possibilities for supply disconnection schemes, i.e., relay disconnection. When designing a disconnection scheme, the performance must be analyzed both with the system power applied and with system power absent. Check for leakage paths and undue voltage drops and try to set up so that disconnection and reconnection will take place as near to the backup voltage as possible.

produce numerous spurious signals, including spurious writes and illegal control signals (i.e., RD and WR both active together).

Bipolar logic devices can produce spikes and glitches as the internal biasing switches off around 3V–3.5V, and the transistors operate in their linear region for a short time. Any such spurious signals, if applied to the RTC, could cause the time data to be corrupted. Systems using 74HC logic and CMOS processors are less stringent in their power failure requirements as the devices tend to work right down to around 2V. Some form of write protection is still required, however.

In order to protect the time data, the system must be physically prevented from writing to the clock when the power supply is not stable. The ideal situation is to ban Write access to the clock before the system +5V starts to fail, and then keep the chip "locked-out" until the power is restored and stabilized. This ideal access control signal is illustrated in Figure 13.

FIGURE 13. RTC Access Lockout Definition

TL/F/6737-14

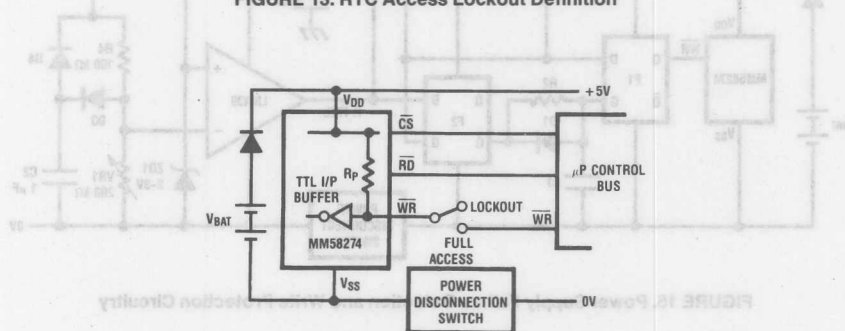

FIGURE 14. Write Protection by Manually Switching WR

TL/F/6737-15

By far the simplest and potentially the most hazard-free method is to use a switch on the WR control line to the clock (Figure 14). This is completely adequate, but requires the intervention of an operator to alter time data or program interrupts.

Some thought must be given to ensuring that the operator cannot accidentally leave the WR line switched in. This may be achieved by the physical access method used (i.e., the machine is impossible to operate or switch off when in the time setting mode, because of the placement of access hatches, etc.) or with software. The switch state could be sensed by trying to alter the data in the Tens of Years counter or Interrupt register just prior to leaving the clock setting routine, and refusing to leave the routine until the WR switch has been opened. The switch condition should similarly be checked whenever the system is initialized or reset.

The physical location of the switch should also be considered for ease of accessibility. How easy the switch is to reach will depend on the system; i.e., in some cases a "tamper proof" clock may be required.

1.4.2 5V Sensing

The circuit of *Figure 15* senses the system 5V supply and prevents access to the clock if the supply falls below 4.2V–4.3V. This circuit should be used where only the system 5V is available for reference. The LM139 comparator and associated components sense the 5V supply and generate the power fail signal (P.Fail). The 74HC75 and components disconnect the WR line.

R3 and ZD1 provide a reference voltage of 2V–3V for the comparator. R4 and VR1 form a potential divider chain sensing the 5V line, and VR1 is adjusted to switch the comparator output at 4.2V–4.3V. An alternative to VR1 would be to use a pair of close tolerance resistors ($\pm 2\%$) with values selected to suit the Zener diode reference used. The combination of R4, D3 and C2 provide an RC time constant to delay the comparator when sensing the return of 5V (to provide the post-failure delay in *Figure 13*). The LM139 has an open-collector output which is held low when 5V is present and is switched off when 5V fails. This line is pulled high by R5 to flag power failure (P.Fail). Since the comparator is a linear device drawing a bias current, it is powered by the system 5V supply to avoid consuming battery power.

One 74HC75 package contains four latches, of which two are used. These are transparent latches controlled by the "G" input. With G high, the latch is transparent and the Q and \bar{Q} outputs follow the Data input. When G is low, the state of Q and \bar{Q} on the falling edge is latched. In this way,

F2 prevents P.Fail from locking out the clock if there is a Write cycle in progress. F1 isolates the WR input on the clock when F2 passes the P.Fail signal. C1, R2 and D1 do not slow the advent of P.Fail, but they cause a delay in the release of the function to mask any comparator noise or oscillation as the comparator switches off or on (i.e., during the undefined supply periods).

D2, C3 and R6 smooth the comparator supply and help it to function effectively. The time constants of the RC networks should be selected to suit the power supply of the system that is used. Comparing the functioning of this circuit with the ideal case of *Figure 13* shows that most of the conditions can be satisfied, except that there is no real pre-failure lock-out period. This cannot be achieved without some form of look ahead power failure.

As an alternative to F1 a permanently powered 74HC4066 analog switch could be used as the isolating component (*Figure 16*). The 74HC4066 does not require pull-up resistors on its inputs as there are no internal CMOS buffers inside this device which must be controlled. The resistor on the WR line is for the benefit of the 74HC75.

Note that both of the devices mentioned must be permanently powered from the battery to be useful in this way. Unused gates in any such device must NOT be used in combinational logic that is not permanently powered. All unused inputs should be tied to V_{DD} or V_{SS} to render them inactive.

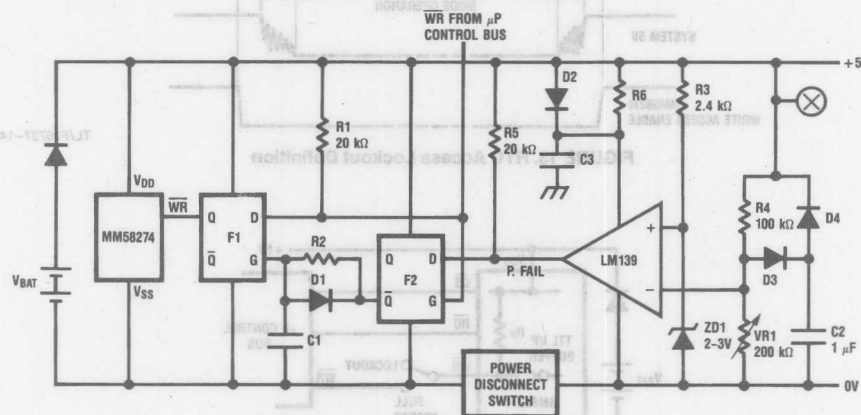

FIGURE 15. Power Supply Failure Detection and Write Protection Circuitry

TL/F/6737-16

1.4.3 Supply Pre-Sense

The same circuit of Figure 15 can be used with unregulated supplies or other voltage lines which will fail before the 5V line. To achieve this, point X is connected to the sensed voltage instead of 5V, and the R_4/VR_1 ratio is adjusted to suit. The major benefit here is that advance warning of an impending 5V failure can be detected, allowing a pre-failure lockout signal to be generated.

Less precision is required to sense the unregulated supply than the system 5V supply. Consequently less complex circuitry can be used to do the detection and this is reflected in the circuit of Figure 17. Most 5V regulators will operate with an input voltage from 7V to 25V. Typically the input voltage is around 9V to 12V, giving some headroom. In Figure 17 this voltage is high enough to drive a current through the Zener diode and turn on transistor TR1, holding P.Fail low. R_{LIM} limits the Zener current. The Zener voltage is selected to switch off before the regulator fails, around 7.5V–8.5V depending on the time constant of the supply. With no current, TR1 switches off and R_P pulls P.Fail high.

When power is re-applied the 5V supply will stabilize before the Zener switches on, removing P.Fail. To provide a longer post-failure lockout period R_{LIM} could be replaced with two resistors and a diode/capacitor delay as in Figure 15.

Figure 18 is another extension of the same basic idea to provide an advance interrupt signal to allow μP housekeeping before the RTC (and CMOS RAM) is locked out. The extra rectifying components D_1 , C_1 and R_1 keep NMI off as long as input power is present. Time constant τ_2 is selected to be at 2–3 times faster than τ_1 , the supply time constant. The interrupt signal is thus asserted before P.Fail.

1.4.4 Switching Power Supplies

Switching power supplies are available which generate power failure signals. This signal may be adequate for direct use as a P.Fail line, but the manufacturer's information should be consulted to determine the suitability of a given power unit. P.Fail must still be gated with the Write signal for the clock, regardless of the actual detection method employed.

1.4.5 Summary

The general guidelines for power fail protection are:

1. Physically isolate the WR input to the clock. The μP cannot be relied upon to logically operate the isolation mechanism.
2. The clock should be isolated before the 5V power line starts to fail, and stay isolated until after it has reestablished.
3. Consider the action of the sensing and protection circuitry if the supplies oscillate or if a momentary glitch occurs.
4. The Power Fail signal must be gated with Write strobes to the RTC. A foreshortened Write may also cause data corruption.
5. Logic components (and ICs in general) should be avoided when designing power failure schemes. Discrete components are far more predictable in their performance when the power supplies are not well defined. The exception to this general rule is when using permanently powered HCMOS logic devices. They will function in a reliable manner down to 2V.

System-powered logic devices cannot be relied on for power failure or Write isolation (not even CMOS).

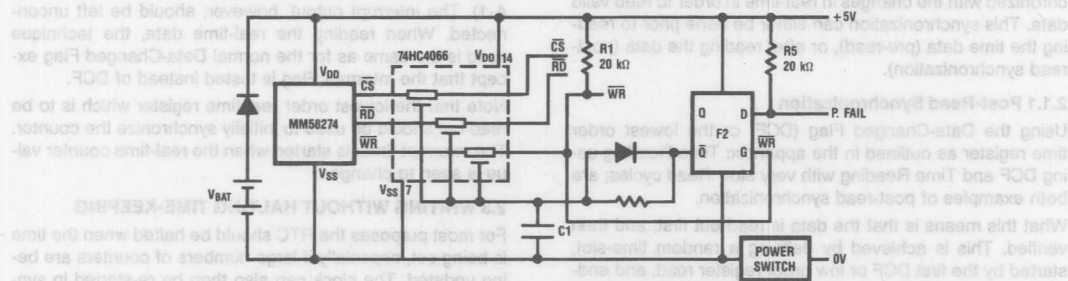

FIGURE 16. F1 Replaced by a 74HC4066 Analog Switch (Pull-Up Resistors Not Required on CS or RD Inputs)

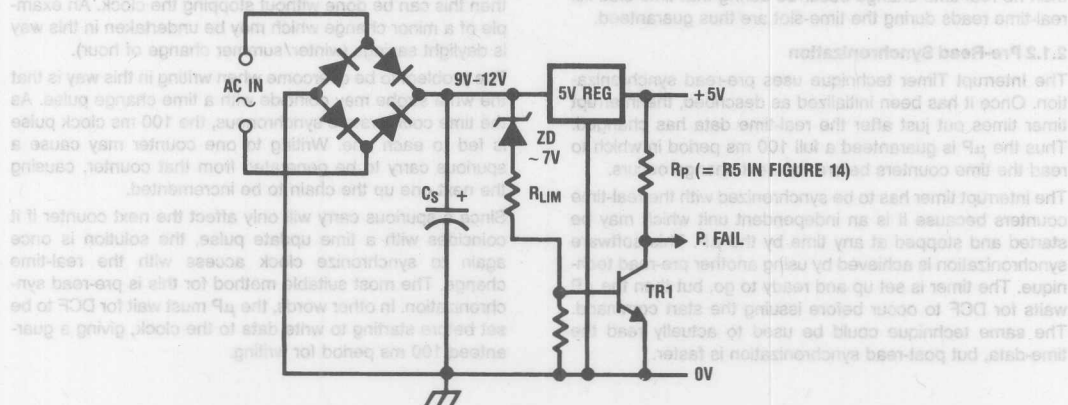

FIGURE 17. Power Fail Signal Generation from Unregulated Supplies

2.4 THE CLOCK AS A μ P WATCHDOG

The interrupt timer can be used as a μ P watchdog circuit, operating on a non-maskable interrupt input to the μ P. The timer is set up in either single or repeat interrupt mode for the watchdog period required: 0.1s, 0.5s or 1 second are probably the most useful times for this. Synchronization with real-time is not required.

In the main program loop the μ P writes to the clock, stopping and then re-starting the interrupt timer. The timer period selected will depend on how long the main loop takes to execute. As long as the μ P continues to execute the loop, no time-outs occur and no interrupts are generated. If the μ P fails for some reason to reset the timer, it eventually times out, generating the initializing interrupt to restore operations.

2.5 THE JAPANESE CALENDAR

Because the MM58274C has a programmable leap year counter, this allows the possibility of programming for the Japanese Showa calendar. The Japanese calendar counts years from the time that the present Japanese Emperor comes to power.

The normal procedure for the MM58274C is to program "the number of years since last leap year." This remains the same whether the clock is loaded with the Gregorian or Showa year. When software is used to calculate the leap year count value from the year, then the formula used must be modified.

The formula for the Gregorian year is:

$$\text{Leap Year Value} = [\text{Gregorian Year}/4] \text{ REMAINDER}$$

Whereas for the Showa year the formula is:

$$\text{Leap Year Value} = [(\text{Showa Year} + 1)/4] \text{ REMAINDER}$$

Leap Year Value is the number from 0 to 3 which is written into the leap year counter, and is the REMAINDER of the integer calculations shown above.

3.0 MISCELLANY

3.1 CONNECTION TO NON Microbus™ SYSTEMS

Adding the MM58274C to non Microbus processors is made fairly straightforward because of the flexibility of the control signal timing. Figure 19 shows two examples of logic to connect to clock to a 6502/6800 microprocessor bus.

Figure 19a the RD and WR inputs are strobed, generating reasonably typical Microbus type control signals. In Figure 19b, CS is used as the strobe signal. There is no particular

advantage to either circuit, they are just variations on the same theme. This circuit flexibility may be used to advantage to save SSI packages in the board design.

FIGURE 19. 6800/6502 μ P Bus Interface

3.2 TEST MODE

Test Mode is used by National Semiconductor when the MM58274C is tested during manufacture. It enables the real-time counters to be clocked rapidly through their full count sequence.

The MM58274C counters are clocked synchronously to simplify μ P access, with ripple carry signals from each counter to the next. In Test Mode some of these carries are intercepted and permanently asserted causing the counters to count each clock pulse. The prescaler is also bypassed so that the counters count every clock applied to the Osc In pin. The Test Mode counter connection is shown in Figure 20.

If Test Mode is to be used for incoming inspection or device verification, then the clock waveform of Figure 21 should be applied to the oscillator input (Osc In, pin 15). The MM58274C uses semi-dynamic flip-flops in the counters which are only fully static when the oscillator input is high. Thus Figure 21 shows that the oscillator waveform is normally high, pulsing low to clock the real-time counters. The time data in the counters changes on the rising edge of Osc In.

When Test Mode is used to test the oscillator frequency, the interrupt timer must be disabled (interrupt register programmed with 00) for the oscillator frequency to appear on the interrupt output. No test equipment should be connected directly to either oscillator pin, as the added loading will alter the characteristics of the oscillator making precise tuning impossible.

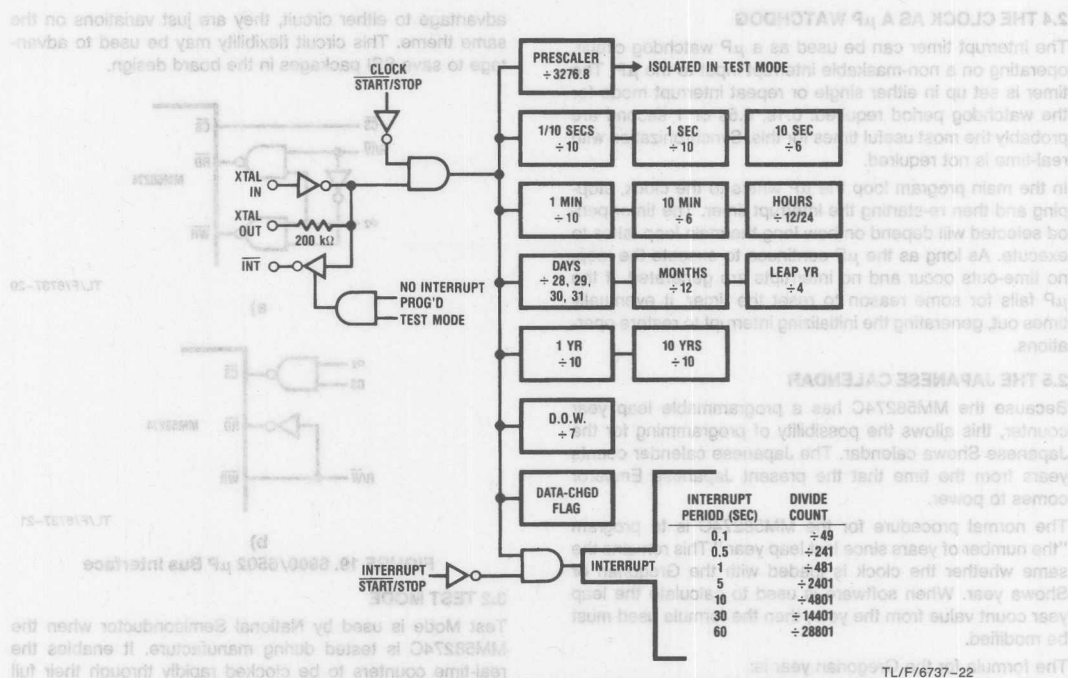

FIGURE 20. Test Mode Interconnection Diagram of Internal Counter Stages

FIGURE 21. Oscillator Waveform for Counter Clocking in Test Mode

The pulse width limits for reliable clocking are shown on the diagram. When running with a 32 kHz crystal, the normal pulse width is 15.26 μ s. With no forcing input, the oscillator will self bias to around 2.5V ($V_{DD} = 5V$). While a few hundred mV swing above and below this level is sufficient to drive the oscillator, for guaranteed test clocking the input should swing between $V_{IH} \geq 75\% V_{DD}$ and $V_{IL} \leq 25\% V_{DD}$.

3.3 TEST MODE AND OSCILLATOR SETTING

When Test Mode is used to set the oscillator frequency, the interrupt timer must be disabled (interrupt register programmed with all 0s) for the oscillator frequency to appear on the interrupt output. No test equipment should be connected directly to either oscillator pin, as the added loading will alter the characteristics of the oscillator making precise tuning impossible.

Note that oscillator frequency will vary slightly as the supply varies between operating and standby voltages. Typically this variation will be around ± 6 seconds per month ($V_{STANDBY} = 2.4V$), slowing at standby voltage. When the clock will spend the greater part of its working life in standby mode, it may prove worthwhile to correct for this in the tuning. This can be done by tuning at standby voltage (by writing the RTC into test mode, then disconnecting it from the system to tune on battery backup). Alternatively, the clock can be slightly overtuned at operational voltage, tuning to 32.7681 kHz.

In a similar way, where the RTC spends equal amounts of time in both operational and standby modes (i.e., powered by day, standby at night), the oscillator may be tuned somewhere between the two conditions. Following these tuning suggestions will not eliminate time-keeping errors, but they will help in minimizing them.

operate using a 15 pF capacitor, but the oscillator will probably need to be retrimmed.

Operating with a 15 pF capacitor will make the oscillator more sensitive to change in the environment, i.e., temperature, voltage, moisture, etc. This will result in lower accuracy in time-keeping. The oscillator is more prone to stopping at low voltage. Oscillation would normally be maintained down to 1.8V–1.9V (although not guaranteed); with a 15 pF load it may only oscillate down to 2.0V–2.1V. It is thus important to check the battery regularly and replace it before the RTC voltage falls below 2.2V.

Where possible the 15 pF capacitor should be replaced by an 18 pF–20 pF capacitor (anywhere in the range 18 pF–20 pF is adequate), or a second 3 pF–5 pF capacitor may be added in parallel with the 15 pF.

Note: When components have been soldered into the oscillator circuit, allow the circuit to cool to room temperature before attempting to re-tune the oscillator.

The change of pin of the tuning capacitor (from OSC Out to Osc In) is not critical.

b) The Supply Disconnection Scheme

The MM58174A uses mostly pull-down devices on its μP inputs to pull the inputs to CMOS levels, and so the 5V power line is disconnected on this device. The two exceptions to this are the \overline{CS} and \overline{WR} inputs which have pull-up resistors to inactivate the internal write strobe. As Figure 5a shows, there is a leakage path through these pins, which in most MM58174A installations are individually isolated.

The largest penalty in inserting an MM58274C into an MM58174A circuit is the battery current that is lost through the pull-up devices. This will increase the typical supply current from 4 μA to 50–100 μA and it is up to the individual user to decide whether or not this drain is tolerable in a particular application.

The most important requirement is that the \overline{WR} input should be electrically isolated or current leakage through pin inputs may force the inputs low enough to cause spurious writes to

be achieved using the same components. In Figure 22 the MM74HC4066 analog switch will do both jobs.

The current drained by the input pull-ups may be minimized with some attention to the data/address driving devices. It is often possible to replace LSTTL devices with standard 7400 series devices and reduce the leakage (at the cost of some increase in operating current). Many 7400 series device outputs lack diodes in the right places to pass leakage currents. LSTTL devices will, for the main part, have these diodes. CMOS devices will always have diodes to both power rails on inputs and outputs.

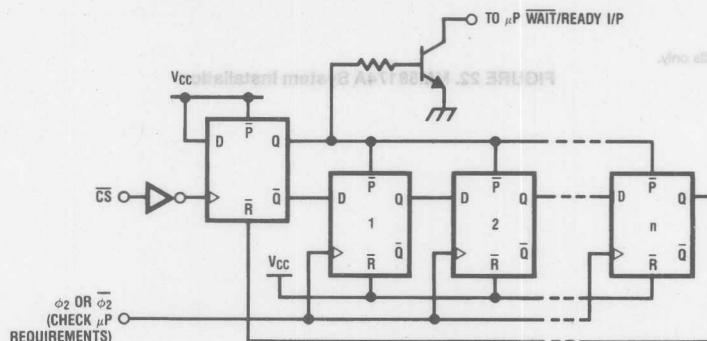

There is no hard and fast rule for this. Where devices from one manufacturer work, the same part from a different one may not. Some trial and error experimentation may prove worthwhile in selected devices.

3.5 WAIT STATE GENERATION FOR FAST μPs

Although the MM58274C has faster access times than the MM58174A, in many cases, the μP will be too fast to directly access the RTC. Figure 23 shows a circuit which will produce wait states of any length required to enable the RTC to be accessed, using the 74HC74 dual D-type flip-flop.

The RTC \overline{CS} signal clocks up a logic 1 on the Q output of the first F/F, removing the Preset from all the other F/Fs and pulling the μP WAIT line low, via the transistor. The other F/Fs 1 to n, form a shift register clocked by the ϕ_2 system clock.

After n ϕ_2 clocks (where n is the number of flip-flops in the shift register) a logic 0 shifts out from the nth F/F, resetting the main flip-flop. The main F/F then presets the shift register and clears the WAIT signal, ready for the next \overline{CS} edge to repeat the cycle. On power-up the delay generator will initialize itself after a maximum of n system clocks have occurred so no reset signal is required. Some μPs demand that a WAIT/READY input is synchronized with ϕ_2 of the system clock. This can readily be achieved by selecting the correct ϕ_2 edge as the clock signal for the shift register chain.

Flip-Flop—MM74HC74 D-Type Latch

FIGURE 23. Access Delay Generator (Clocked Wait State Generator)

APPENDIX A-1. READING VALID REAL-TIME DATA

TIME READING USING DCF

Using the Data-Changed Flag (DCF) technique supports microprocessors with block move facilities, as all the necessary time data may be read sequentially and then tested for validity as shown below.

1. Read the control register, address 0: *This is a dummy read to reset the data-changed flag (DCF) prior to reading the time registers.*
2. Read time registers: *All desired time registers are read out in a block.*
3. Read the control register and test DCF: *If DCF is still clear (logic 0), then no clock setting pulses have occurred since step 1. All time data is guaranteed good and time reading is complete.*

If DCF is set (logic 1), then a time change has occurred since step 1 and time data may not be consistent. Repeat steps 2 and 3 until DCF is clear. The control read of step 3 will have reset DCF, automatically repeating the step 1 action.

TIME READING USING AN INTERRUPT

In systems such as point-of-sale terminals and data loggers, time reading is usually only required on a random demand basis. Using the data-changed flag as outlined above is ideal for this type of system. Where the μP must respond to any change in real-time (e.g., industrial timers/process controllers, TV/VCR clocks or any system where real-time is displayed) then the interrupt timer may be for time reading. Software is used to synchronize the interrupt timer with the time changing as outlined below:

1. Select the interrupt register (write 2 or 3 to ADDR0).
2. Program for repeated interrupts of the desired time interval (see Table IIb in Appendix A-2): *Do not start the timer yet.*
3. Read control register AD0: *This is a dummy read to reset the data-changed flag.*

4. Read control register AD0 repeatedly until data-changed flag is set.
5. Write 0 or 2 to control register. Interrupt timing commences.

When interrupt occurs, read out all required time data. There is no need to test DCF as the interrupt "pre-synchronizes" the time reading already. The interrupt flag is automatically reset by reading from ADDR0 to test it. In repeat interrupt mode, the timer continues to run with no further μP intervention necessary.

TIME READING WITH VERY SLOW READ CYCLES

If a system takes longer than 100 ms to complete reading of all the necessary time registers (e.g., when CMOS processors are used or where high level interpreted language routines are used) then the data-changed flag will always be set when tested and is of no value. In this case, the time registers themselves must be tested to ensure data accuracy.

The technique below will detect both time changing *between* read strobes (i.e., between reading tens of minutes and units of hours) and also time changing *during* read, which can produce invalid data.

1. Read and store the value of the *lowest* order time register required.
2. Read out all the time registers required. The registers may be read out in any order, simplifying software requirements.
3. Re-read the lowest order register and compare it with the value stored previously in step 1. If it is still the same, then all time data is good. If it has changed, then store the new value and go back to step 2.

In general, the rule is that the first and last reads *must* both be of the lowest order time register. These two values can then be compared to ensure that no change has occurred. This technique works because for any higher order time register to change, all the lower order registers must also change. If the lowest order register does not change, then no other register has changed either.

National Semiconductor
Application Note 588
James Petrie

This application note applies to the DP8570A, DP8571A, DP8572A, and DP8573A. With respect to the DP8573A, only the discussion of the 32.768 kHz oscillator applies.

The intrinsic properties of quartz make it a uniquely simple device for highly accurate and stable frequency generation. Crystals are not a primary frequency standard but used with care can provide stability far in excess of most requirements. Various configurations of oscillator circuits exist to enable the designer to implement such a source. Its performance, however, is largely dependant on the environment and its associated electrical components. Firstly, consider the basic element—the crystal itself.

A quartz crystal is a mechanically moving system and is very dependant on the environment in which it is operating. The encapsulation will therefore critically affect the long term stability and is a major cause of crystal aging. The choice of crystal holder is important; there are four main types:

TABLE I. Crystal Types

Crystal Type	Aging
Solder Sealed	100 ppm/year
Resistance Welded	4 ppm/year
Cold Welded	2 ppm/year
Glass Enclosed	1 ppm/year

The solder seal units have relatively poor aging characteristics and have now been superseded by resistance welded units. The other three types offer good aging characteristics.

The exact frequency of oscillation is also dependent on the ambient temperature, therefore another important feature to bear in mind when choosing a crystal is the Frequency/Temperature characteristic. If a typical manufacturer's specification is consulted it can easily be seen that there is quite a variation in stability for different temperatures; stabilities of ± 20 ppm over a range of -20°C to $+70^{\circ}\text{C}$ are not uncommon.

The capacitors are the components that are most likely to affect the accuracy of the oscillator and care must also be exercised in selection. Since the oscillator plays such an important part in the accuracy of the DP8570A (both timers and real-time selection) it is vital to use good quality examples. There are various types of capacitors available which offer close tolerances and good temperature coefficients. Any of these would be suitable in this application.

TABLE II. Capacitor Types

Capacitor	Typical Tolerance	Typical Temp Coef.
Polycarbonate	5%	50 ppm/ $^{\circ}\text{C}$
Ceramic	10%	30 ppm/ $^{\circ}\text{C}$
Silver Mica	1%	35 ppm/ $^{\circ}\text{C}$

Trimmer capacitors with polypropylene dielectrics give a poorer temp coefficient when compared with those above (typically 300 ppm/ $^{\circ}\text{C}$ approx). However, they offer the benefit of allowing the oscillator to be tuned for optimum results.

The oscillator components must be built as close as possible to the pins of the device so as to minimize stray capacitance. The oscillator circuit pins are high impedance nodes and are susceptible to noise coupling from adjacent lines, hence the oscillator should also be surrounded by a guard ground. The maximum length of PCB tracks on either pin is 2.5 cm; longer tracks will reduce oscillator stability.

The accuracy and stability of the oscillator is dependent on various factors; principally external components used, ambient temperature and aging. The information given above is included as a guide to the problems encountered in designing a stable oscillator circuit. Manufacturers specifications should be consulted for more comprehensive data before embarking on designs.

Figures 4a and 4b show typical curves of frequency temperature characteristics of tuning fork and A-T cut crystals.

DP8570 OSCILLATORS

For the DP8570A, the configuration of the crystal oscillator is the standard Pierce parallel resonant oscillator arrangement which has been designed for low power consumption and high stability, this is shown in Figure 1. The external components required are a crystal and two capacitors to provide the correct output loading. The configuration recommended is that of a fixed capacitor and a variable trimmer capacitor, adjusting the trimmer allows the crystal loading (and hence the oscillator frequency) to be fine tuned for optimum results. All other components are on-chip.

The DP8570A has three selectable oscillator frequencies which can be used as a clock source, these are split into two groups, there is the high frequency oscillator and the low frequency oscillator. When programmed for low frequency operation, a small low power inverter is selected along with the relevant bias and feedback resistors, similarly for high frequency operation a larger inverter with a different pair of resistors is selected, Figure 1 illustrates the basic concept.

A fourth option is available, but this is for driving the OSC IN pin with an external 32.768 kHz signal. In this mode the OSC OUT pin is not connected.

The three different crystals frequencies are; 32.768 kHz, 4.194304 MHz or 4.9152 MHz, see data sheet for full explanation of crystal selection. The recommended capacitance values for these crystals are shown in Table 3.

TABLE III. Oscillator Capacitors

	Variable (Osc In)	Fixed (Osc Out)
32.768 KHz	2 pF–22 pF	47 pF
4.194304 MHz	0 pF–80 pF	68 pF
4.9152 MHz	29 pF–49 pF	68 pF

For optimum performance it is recommended that the variable capacitance is placed on OSC IN. The typical value quoted for the trimmer capacitor is the value that the manufacturer quotes for these commercially available types and which will allow accurate tuning of the oscillator. It is not meant to show the range or tolerance of an equivalent fixed value.

This range is also based on a typical circuit board layout and may have to be changed depending on the parasitic capacitance of the printed circuit board or fixture being used. In all cases the load capacitance specified by the manufacturer is what determines proper oscillation. This load capacitance is the series combination of capacitance on each side of the crystal with respect to ground.

It is perfectly feasible to use two fixed values, however this will not allow optimum setting of the oscillator frequency. For example a 12 pF fixed capacitor with a tolerance of

$\pm 10\%$ is a good substitute for the trimmer capacitor in a 32.768 kHz application.

The HF oscillator has been designed primarily for 4 MHz operation therefore greater care should be exercised when choosing external components for 5 MHz operation. The best configuration for the 5 MHz operation is to use a fixed capacitor in parallel with a trimmer capacitor on the OSC IN pin. Note the small variation of the OSC IN capacitance required to ensure correct start-up and oscillation.

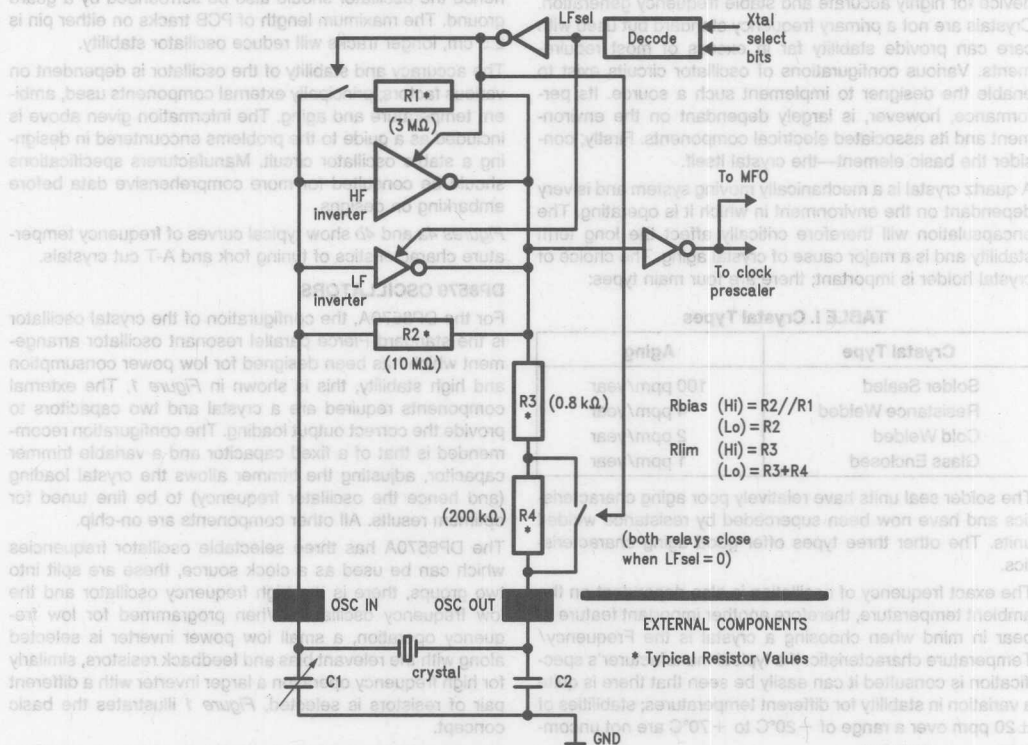

FIGURE 1. DP8570A Oscillator

The capacitor are the components that must also be selected in selection. Since the oscillator plays such an important part in the accuracy of the DP8570A (both times and real-time selection) it is vital to use good quality capacitors. There are various types of capacitors available which offer close tolerances and good temperature coefficients. Any of these would be suitable in this application.

TABLE III. Oscillator Capacitors

Fixed (Osc Out)	Variable (Osc In)	Typical Values
47 pF	2 pF - 22 pF	32.768 KHz
88 pF	0 pF - 80 pF	4.19404 MHz
88 pF	22 pF - 49 pF	4.9152 MHz

For optimum performance it is recommended that the variable capacitor is placed on OSC IN. The typical values quoted for the trimmer capacitor is the value that the manufacturer quotes for these commercially available types and which will allow accurate tuning of the oscillator. It is not meant to show the range or tolerance to an equivalent fixed value.

TABLE II. Capacitor Types

Capacitor	Typical Temp Coef	Tolerance
Polypropylene	50 ppm/°C	5%
Ceramic	30 ppm/°C	10%
Silver Mica	35 ppm/°C	1%

Trimmer capacitors with polypropylene dielectric give a better temp coefficient when compared with those above (typically 300 ppm/°C approx). However, they offer the benefit of allowing the oscillator to be tuned for optimum results.

CALIBRATION ROUTINE

A calibration routine is necessary to maintain the oscillator output at the desired accuracy and thus optimize time keeping accuracy. The problem with calibrating these types of circuits is accessing the oscillator frequency. No test equipment should be connected directly to either oscillator pin, as the added loading will alter the characteristics of the oscillator making accurate tuning impossible.

For the DP8570A, the calibration can be accomplished using the Multi-Function Output (MFO) pin of the device. The MFO pin can be programmed for several different functions.

1. Buffered Crystal Output
2. Second Interrupt Pin
3. Timer 0 Output

The crystal frequency can be made available at this pin. Since it is buffered a measuring device can be connected directly to it and the oscillator will remain unaffected. Further, this task can be accomplished under software control and without entering test mode.

Adjustment of the oscillator can be carried out using the setup shown in Figure 2, by tuning the capacitance C1 the user can see what effect this variation has on the frequency value.

The following sequence of operations is the calibration routine that is required when setting up the oscillator:

1. Main Status Register. Write 01xx xxxx. Select RS = 1, PS = 0.
2. Output Mode Register. Write 1011 xxxx. Select MFO as buffered oscillator with push/pull and active high configuration.
3. Real Time Mode Register. Write 0000 0000. Select desired crystal frequency (32.768 kHz).
4. Main Status Register. Write 00xx xxxx. Select RS = 0, PS = 0.
5. Periodic Flag Register. Write 00xx xxxx. Select Battery backed mode and ensure not in test mode (bit D6 = 1 for single supply mode).
6. Monitor the MFO pin with an oscilloscope and observe that the oscillator is functioning at approximately its correct frequency.
7. Connect a frequency measuring instrument to the MFO pin.

Care should be exercised when choosing an instrument with which to measure the frequency. To achieve accuracies of 10 ppm or greater high resolution high accuracy instruments only should be used. Instruments recommended are HP 5334A or PHILLIPS PM 6654.

8. Adjust the trimmer capacitor until the desired accuracy is obtained (2 ppm should be achievable). Figure 5 shows the relationship between frequency error or in ppm vs time gained/lost in minutes/year.

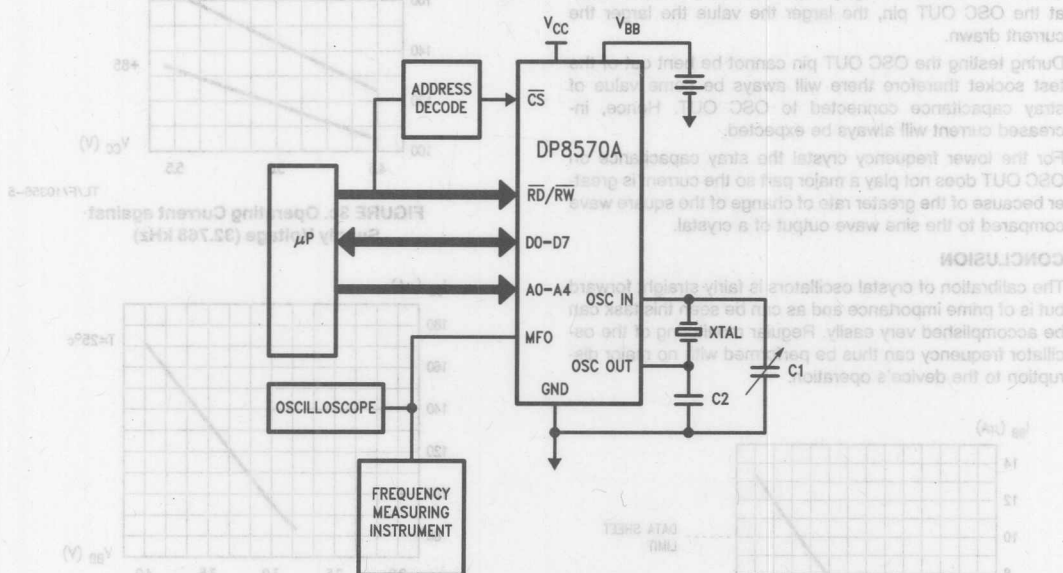

FIGURE 2. Calibration Setup

TEST CONSIDERATIONS

Under test conditions a crystal cannot be used as there is no control over its output, a pulse generator must be used to clock the device in a controlled manner. This presents correlation problems when measuring I_{DD}/I_{BB} because the clock signal used in testing is a square wave and the values for current consumption will be different. The graphs in Figure 3 show the values of operating current (I_{DD}) and standby current (I_{BB}) for different temperatures, voltage and crystal.

The graph that is the most important is I_{BB} at 32.768 kHz, the data sheet states that no more than 10 μA of standby current will be consumed across temperature for $V_{BB} = 3V$. Typical values at $T = 25^\circ C$ ($V_{BB} = 3V$) as measured on the tester are approximately 4 μA , this compares with 6 μA as measured with a crystal. If a user wishes to use the 10 μA specification, he must limit the battery supply to approximately 3.5V, (see Graph 3a). Graph 3b shows that the standby current does not vary a great deal with temperature.

For the I_{CC} measurement a typical value at $V_{CC} = 5.5V$, $T = 25^\circ C$ is 160 μA as measured with a tester as opposed to a value of 162 μA with a crystal. There is little difference between the two values. The same cannot be said for the high frequency crystals, the tester figure of 210 μA for $V_{CC} = 3V$, $T = 25^\circ C$ compared to only 97 μA for a crystal. The reason for this is as follows, when forcing with a clock source the current is largely dependent on the capacitance at the OSC OUT pin, the larger the value the larger the current drawn.

During testing the OSC OUT pin cannot be bent out of the test socket therefore there will always be some value of stray capacitance connected to OSC OUT. Hence, increased current will always be expected.

For the lower frequency crystal the stray capacitance on OSC OUT does not play a major part so the current is greater because of the greater rate of change of the square wave compared to the sine wave output of a crystal.

CONCLUSION

The calibration of crystal oscillators is fairly straight forward but is of prime importance and as can be seen this task can be accomplished very easily. Regular monitoring of the oscillator frequency can thus be performed with no major disruption to the device's operation.

Test Considerations

Primarily the test mode is used by National Semiconductor to ease the testing of device at manufacture. However, some users may wish to implement testing of devices prior to being used in designs. The purpose of this application note is to give the user insight into what is involved when testing the DP8570A Timer Clock Peripheral (TCP). The complete range of test mode features is presented here along with notes on how to use them. General testing guidelines are also given which should help the user to avoid some of the pitfalls at the design-in stage.

INTRODUCTION

The real-time clock section of the DP8570A is a series of cascaded registers. To test the correct roll-over of each register in this configuration would take a very long time. For example, if clocked in real-time (100 Hz), testing would take 100 years to complete, obviously this is unacceptable.

Similar problems exist when testing the timers. Each timer is 16 bits wide. If it were to be tested in normal operation, 65536 (2^{16}) pulses are required to produce a cycle in the 16th bit in the chain. This will result in an intolerable increase of testing time.

There are further test considerations with the timer prescaler section of the device. These sections contain frequency divider circuits. The easiest way to test these dividers is to measure the frequency of the output and relate it to the frequency of the input. However, with some standard production machines it is difficult to measure frequency. Therefore it will be difficult to check the various outputs of the timer prescaler.

The actual method of testing these prescalers is to apply a set number of pulses to the input of the divider and monitor the output for a change of state. For example, to test the divide by 32000 counter, that number of pulses would have to be applied to produce an output pulse. If the normal timer prescaler configuration is used it will take one full second waiting for the divide by 32000 counter to cycle.

TEST MODE FEATURES

To overcome testing difficulties of the types discussed a test configuration has been designed into the device, which

can be implemented via software. Due to the complex nature of the TCP a complete register is required to control the various test functions. This register is situated at RAM location 1F (hex) on page 0 (see datasheet for details of addressing).

The byte associated with this address is normally a general purpose RAM location. When in test mode, the register can be programmed to implement various test configurations. To enable these functions the test mode enable bit (D7) in the Periodic Flag Register (PFR) must be programmed high. For normal operation this bit must be programmed low. The Test Mode Register configuration is shown in Figure 1.

D7	D6	D5	D4	D3	D2	D1	D0
OSF DISABLE	CRB1	CRB0	SRB1	SRB0	EMC	CTR TEST	DIR CLOCK

FIGURE 1. Test Mode Register

The functions of the various bits in the test mode register are outlined below. Bits D0,D1 are for the real time and associated sections, while bits D2 to D6 are dedicated for timer use. D7 is for general use.

DIR CLOCK: This is the Direct Clock bit. When programmed high, the oscillator dividers (32 kHz and 1 kHz) and the pulse subtractor in the clock prescaler are bypassed. Thus the counters in the real-time section may be clocked directly from a signal presented to the OSC IN pin. To implement the by-pass correctly, the frequency select bits D6,D7 in the Real-Time Mode Register, must be programmed such that the 4 MHz and 5 MHz divider chains are also disabled (see Figure 2). The correct programming for this is D6,D7 = 0 or D6,D7 = 1.

The 4 MHz and 5 MHz dividers can be tested in isolation using the following:

DIR CLOCK = 1 and D6 = 1 for 4 MHz,
DIR CLOCK = 1 and D7 = 1 for 5 MHz.

The output of these dividers will then be connected directly to the 1/100 second counter.

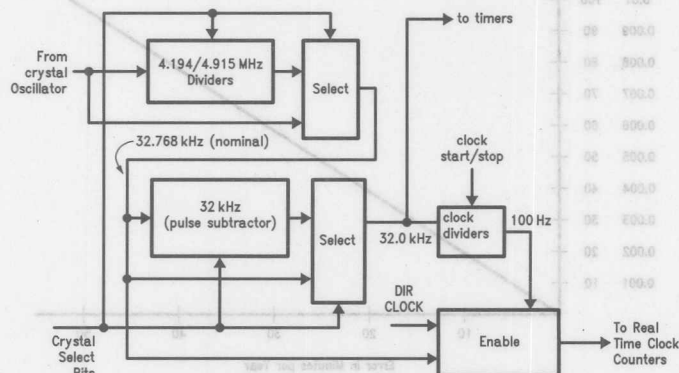

FIGURE 2. Clock Prescaler (with Test Bit)

TL/F/10357-1

CTR TEST: This is the Counter Test bit. When programmed high this bit re-configures the real-time counters into the test mode configuration (see Figure 3). These counters can then be clocked in parallel thus reducing the test time.

Note that the normal maximum operating frequency of these counters is 100 Hz and the low frequency oscillator is designed to work at approximately 32 kHz. Therefore if fast clocking via the OSC IN pin is attempted serious signal degradation will occur, making testing impossible. For these reasons it is recommended that for a $V_{BB} = 3V$, a maximum clock rate of 200 kHz (2.5 μs pulse width) is used on all tests where the OSC IN pin provides the clock source. When testing the device using clock bursting, the clock must be a return-to-one signal. It is not recommended that the OSC OUT pin be used as a clock source, and must not be connected.

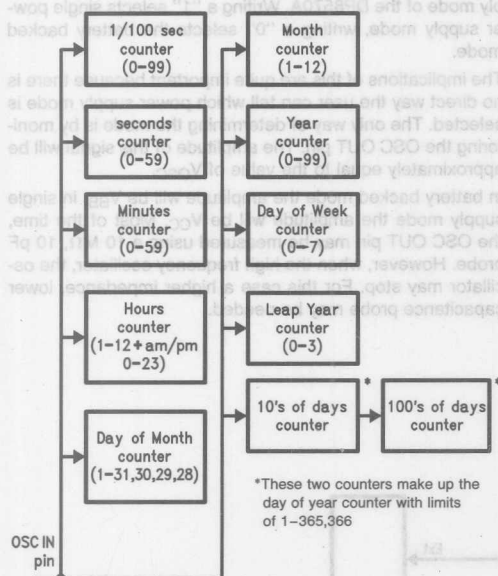

FIGURE 3. Real Time Counters, Test Mode Configuration

EMC: This is the Enable MSB Clock bit. When programmed high it enables the most significant bytes (MSBs) of both 16-bit counters to be clocked directly. Note that the LSB's of the counters must contain 00(hex) for this to be accomplished correctly. This allows the timers to be tested in two halves, which will give a total of $2 \times (2^8)$ possible states instead of 2^{16} significantly reducing the test time.

SRB0: This is the Signal Route Bit for timer 0 prescaler. When programmed high this bit routes the selected clock to the timer 0 output.

SRB1: This is the Signal Route Bit for timer 1 prescaler. When programmed high this bit routes the selected clock to the timer 1 output.

The inclusion of the "SRB" bits means that a more modular approach to timer testing is achieved because the timer prescalers can be tested in isolation.

The clock select bits in the Timer Control Register are used to route the required clock to the multiplexer output "selected clock", of the prescaler, see Figure 4. Note that timer 0 output is accessed using the Multifunction Output (MFO)

pin, see datasheet for details. However, timer 1 output can be accessed directly using the Timer 1 Output (T1) pin.

CRB0: This is the Crystal Route Bit for timer 0 prescaler. When programmed high this bit routes the external crystal frequency to the dividing counters in timer 0 prescaler which are normally driven by the internal 32.0 kHz signal. See Figure 2.

CRB1: This is the Crystal Route Bit for timer 1 prescaler. When programmed high, this bit routes the external crystal frequency to the dividing counters in timer 1 prescaler which are normally driven by the internal 32.0 kHz signal.

The "CRB" bits allow all the timer prescaler dividers to be clocked directly from the OSC IN pin. This allows fast clocking of these circuits plus allowing a known number of pulses to be input. Note that the frequency select bits in the Real Time Mode register need to be programmed correctly for this section as well (D6,D7 = 0).

OSF DISABLE: This is the OSC Fail Disable bit. When programmed high this bit causes the OSC FAIL detect circuitry in the clock prescaler to be disabled.

One of the features of the DP8570A is its ability to detect when an oscillator fail has occurred. Oscillator failure is indicated by reading bit D6 in the Periodic Flag Register. When an oscillator fail is detected four functions are performed.

1. The OSC fail flag is set.
2. The clock start/stop bit (CSS) in the Real Time Mode register is reset, preserving the time that the oscillator stopped.
3. Overrides the lockout circuitry ensuring that the processor interface is not locked out when an oscillator fail has occurred.
4. Presets battery bit (D6) in PFR (selects the single power supply mode).

Under test conditions a crystal cannot be used because there is no control over its output. A pulse generator must be used to clock the device in a controlled manner. Obviously, under these single-step conditions the oscillator fail circuitry will detect a lack of oscillation and perform the functions mentioned. Therefore for certain tests it will be necessary to disable the effect of OSC fail (where CSS must remain active for example), this is accomplished using the OSC Fail Disable bit.

To get access to the OSF Disable bit, the test mode enable bit (D7 in the PFR) must be written high first. The order is important. The OSF Disable bit must also be programmed back to zero when testing is complete. This is to avoid drawing excess current in standby mode. When initial power is applied, this bit has been designed to power-up in the inactive state, ensuring that the TCP will not enter a state of permanent lockout when power is applied.

The implications of function 4 are also important when considering the fact that a pulse generator is used to provide the clock source. The amplitude of the output signal should be equal to the power supply of the oscillator (V_{OSC}).

In battery backed mode $V_{OSC} = V_{BB}$
In single power supply mode $V_{OSC} = V_{CC}$

When testing the device in battery backed mode, and using single pulses, the following steps are necessary to ensure that the device is in the correct mode.

MSR	00	RS = 0
PFR	80	Test Mode Enable
TST	80	OSC Fail Disable Bit
PFR	80	Battery Bit and Test Mode

The reason the PFR has to be written twice is that the OSC FAIL signal will preset the single supply bit (D6) and has to be disabled before D6 can be written to.

Read/Write Considerations

In the DP8570 the bits in the address space consist not only of normal read/write bits but also flags, read-reset flags, write-1 reset flags and a dual function bit. The user should be aware of these when attempting to read/write to the device.

Read/Write Bits

MSR	D6,D7 Only
TCR0, TCR1	D0-D7
PFR	D7 Only
IRR	D0-D5, D7
RTMR	D0-D7
(Bit D3 will remain at 0 unless in test mode or the oscillator is running)	
OMR	D0-D7
ICR0, ICR1	D0-D7
1/100 sec	D0-D7
SECONDS	D0-D6 (D7 Always 0)
MINUTES	D0-D6 (D7 Always 0)
HOURS 24 hr	D0-D5 (D6,D7 Always 0)
HOURS 12 hr	D0-D4
(D5,D6 Always 0, D7 = am/pm Bit)	
DAY of MONTH	D0-D5 (D6, D7 Always 0)
MONTH	D0-D4 (D5-D7 Always 0)
YEAR	D0-D7
DAY of YEAR	D0-D7
100's DOY	D0, D1 (D2-D7 Always 0)
DAY of WEEK	D0-D2 (D3-D7 Always 0)

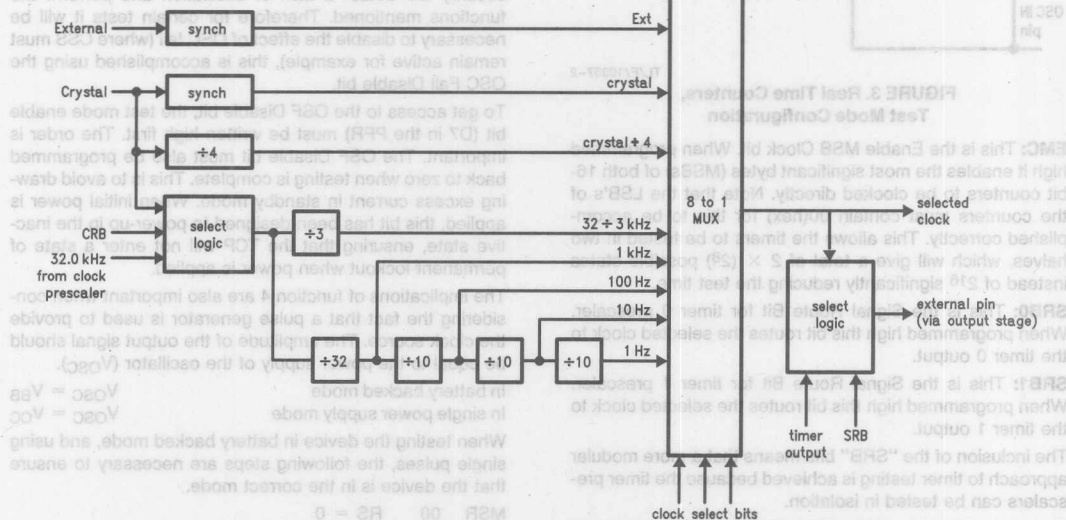

FIGURE 4. Timer Prescaler (with test bits)

The rest of the address locations are all read/write but certain precautions need to be observed to get a correct response. It is recommended that the control section is reset to all zeros before attempting to write to the rest of page 0 locations.

Flags

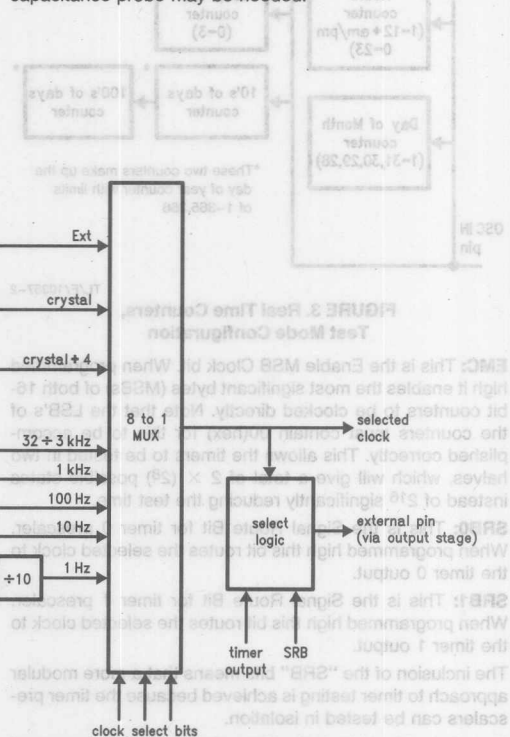

The flags are read only and are set and reset by events inside the device. They are situated at the following locations.

Batt Low Flag	D6 of IRR
Power Fail Flag	D1 of MSR
Interrupt Status Flag	D0 of MSR
Dual Function	D6 of PFR

When READ, D6 of the PFR will give the contents of the OSC FAIL flag. When WRITTEN, D6 sets up the power supply mode of the DP8570A. Writing a "1" selects single power supply mode, writing a "0" selects the battery backed mode.

The implications of this are quite important because there is no direct way the user can tell which power supply mode is selected. The only way of determining the mode is by monitoring the OSC OUT pin. The amplitude of this signal will be approximately equal to the value of V_{OSC} .

In battery backed mode the amplitude will be V_{BB} , in single supply mode the amplitude will be V_{CC} . Most of the time, the OSC OUT pin may be measured using a 10 M Ω , 10 pF probe. However, when the high frequency oscillator, the oscillator may stop. For this case a higher impedance, lower capacitance probe may be needed.

TLF/10357-3

The only way of determining the mode is by monitoring the OSC OUT pin. The amplitude of this signal will be approximately equal to the value of V_{OSC} .

In battery backed mode the amplitude will be V_{BB} , in single supply mode it will be V_{CC} . This technique is helpful when using either a pulse generator or crystal as the clock source. However, care should be taken if probing OSC OUT when a crystal is used, as the probe capacitance could stop the oscillation. As a minimum, a 10 Meg, 10 pF probe is recommended.

The read-reset flags are situated at D0–D5 of the PFR and are read only. Internal events inside the device set the flags and they are reset when read.

The write-1 reset flags are situated at D2–D5 of the MSR. They can be read as a 1 or 0, and are set by internal events inside the device. Writing a 0 to these bits will have no effect. Writing a 1 will reset these flags.

CONCLUSION

The purpose of this note is to provide some insight into the complexities of testing the DP8570A. It shows how various tests can be carried out efficiently by designing testability into a device. The actual testing implemented by the user can be simple or comprehensive and only those features required need be utilized.

Flexible Timers on the DP8570A and DP8571A

1.0 INTRODUCTION

The DP8570A/71A/72A/73A family are Real Time Clock devices for use in microprocessor based systems. They are fast access low power devices with power fail protection, standby battery operation, multiple interrupts and RAM. In addition, the DP8570A and DP8571A "Timer Clock Peripherals" have two independent 16-bit binary countdown timers.

This application note deals primarily with using the timers on the DP8570A. It has dedicated timer pins; an external clock pin with up to 10 MHz operation, a hardware gate/hold pin per timer and a timer output pin. Further information is given on the DP8571A which does not have these pins, hence reducing the pin-count, but has the additional feature of being able to cascade the timers. This gives use of a timer of up to 32 bits.

The timers of both Timer Clock Peripherals have four modes of operation, seven crystal derived internal clock frequencies, programmable output/interrupts and standby operation.

2.0 DP8570A TIMERS (Figure 1)

Each timer, T0 and T1, has two 8-bit registers (MSB/LSB) accessed in page 0 of the DP8570A internal memory. The number in these registers is loaded into a 16-bit counter when the timer is started and the counter is decremented by the selected input clock, hence controlling the timer output. Resetting the timer start/stop bit stops the timer and puts its output into its inactive state (high or low depending on how

National Semiconductor

Application Note 595

Jim Mitchell

the output is programmed). Every time the start/stop bit is set the initial value in the MSB/LSB registers is reloaded by the next selected timer input clock. A gate signal, however, is also required in mode3 before loading occurs.

Normally when accessing the data at the address of the MSB/LSB registers, only the initial load value will be read. However, if the timer read bit is set, the MSB/LSB of the counter itself will be read. This allows the user to read the counters *on-the-fly*, without disturbing timing.

The user might encounter a problem when the timer read bit is set just as the counter is reloading. In this case there is a possibility of erroneously reading a value FFhex. The user should choose initial register values other than FFhex, reject any FFhex read *on-the-fly* and try the read operation again.

The T0 and T1 timer start/stop bit and timer read bit are in their respective timer control registers. Each timer control register contains the following bits:

- D0 Timer Start/Stop
- D1 Mode Select M0
- D2 Mode Select M1
- D3 Input Clock Select C0
- D4 Input Clock Select C1
- D5 Input Clock Select C2
- D6 Timer Read
- D7 Count Hold/Gate

The programming of this and other timer related registers is described in Section 3.0.

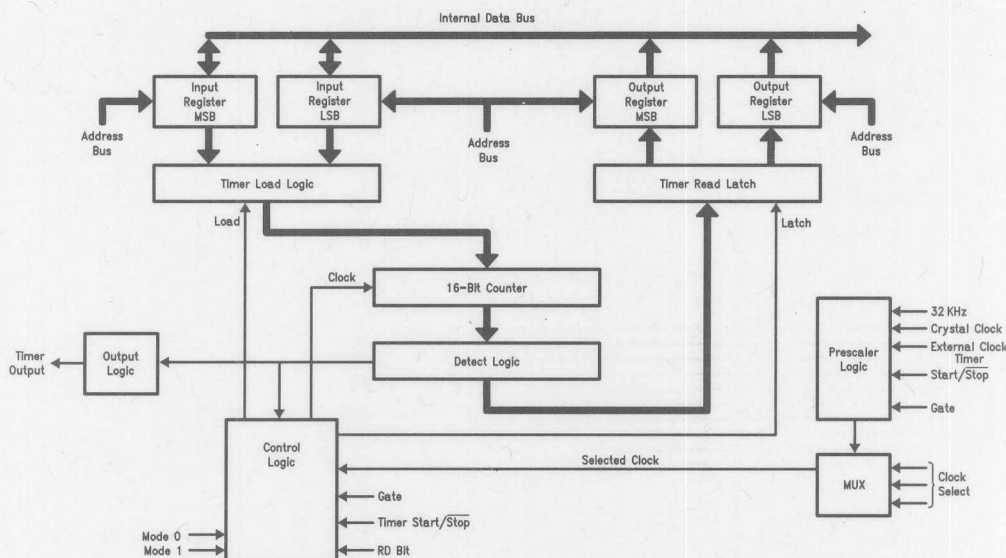

FIGURE 1. DP8570A Timer

TL/F/10372-1

3.0 USING DP8570A TIMERS

The following steps should be considered when using the DP8570A timers.

- Mode selection to give desired output waveform.
- Input and frequency selections to give countdown rate of timer.
- Output and interrupt selections.
- Standby conditions (if backed up).

3.1 Mode Selection

Four output waveforms are obtainable from the DP8570A, selected by two bits in the timer control registers (Table I).

TABLE I. Timer Control Registers Mode Bits D2, D1

M1	M0	Mode
0	0	0
0	1	1
1	0	2
1	1	3

3.1.1 MODE 0: Single Pulse Generator (Figure 2)

In this mode, a timer output will become active and its counter will decrement once its start/stop bit is set. As soon as the count reaches zero, the start/stop bit is automatically reset and the output returns to its inactive state. Hence the active time (pulse width) is

$$\text{Timer Clock Period} \times \text{Number in Counter.}$$

The pulse width can be increased by temporarily stopping the clock in two ways. One is to set the timer count hold/gate bit and the other is to put the respective G input pin to a logic one state. The count-down is resumed once the count hold/gate bit is reset or G input is returned to logic zero.

3.1.2 MODE 1: Rate Generator (Figure 3)

In this mode, a timer output will become active and its counter will decrement once its start/stop bit is set. When the count reaches zero, the output goes inactive for one timer clock period. The counter is reloaded with the number in the registers. On the next clock the output goes active again and the sequence continues until the start/stop bit is reset. The period is

$$\text{Timer Clock Period} \times (\text{Number in Counter} + 1)$$

M1	M0	Mode
0	0	0
0	1	1
1	0	2
1	1	3

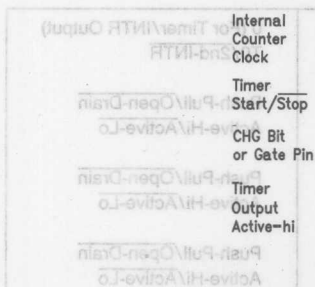

FIGURE 3. Mode 1—Rate Generator

and the (inactive) pulse width is the timer clock period. As in mode 0, the count-down can be suspended by setting the count hold/gate bit or using the G input pin.

3.1.3 MODE 2: Square Wave generator (Figure 4)

In this mode, a timer output will become active and its counter will decrement once its start/stop bit is set. On the clock after the count reaches zero, the output goes inactive. The counter is reloaded with the number in the registers and the counter will decrement to zero again before returning to the active state. The sequence continues until the start/stop bit is reset. The period is

$$2 \times \text{Timer Clock Period} \times (\text{Number in Counter} + 1)$$

with a 50% duty cycle. As in mode 0, the count-down can be suspended by setting the count hold/gate bit or using the G input pin.

3.1.4 MODE 3: Retriggerable One Shot (Figure 5)

In mode 3, a timer output will not become active as soon as its start/stop bit is set. A trigger is also required to start a pulse. The trigger is either setting the count hold/gate bit or the rising edge of a pulse on the respective G input pin. (A trigger pulse as short as 25 ns can be used.) This trigger puts the timer output in the active state and initiates the timer count-down sequence. When the count reaches zero, the output goes inactive until another trigger is given. The pulse width is

$$\text{Timer Clock Period} \times \text{Number in Counter.}$$

If another trigger is given while the timer is still decrementing, the initial number from the timer registers is reloaded thus extending the pulse. The DP8570A remains operational in this mode until the start/stop bit is reset.

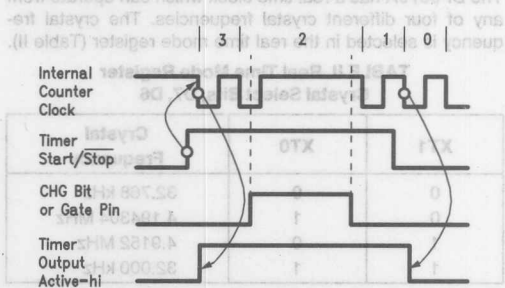

FIGURE 2. Mode 0—Single Pulse Generator

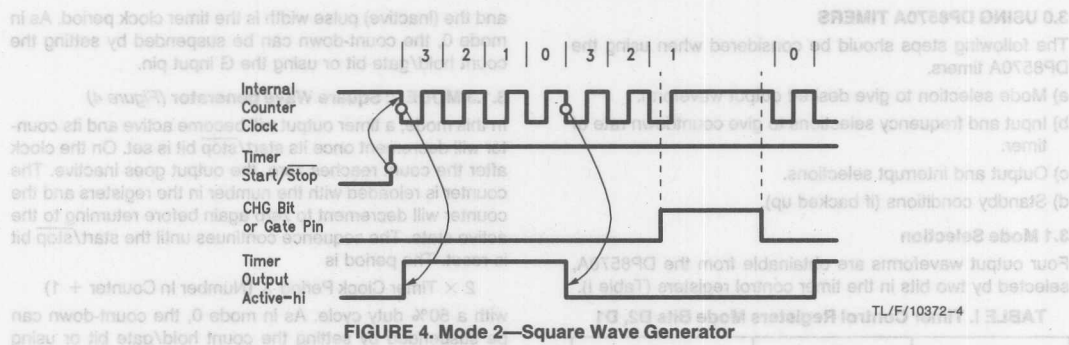

FIGURE 4. Mode 2—Square Wave Generator

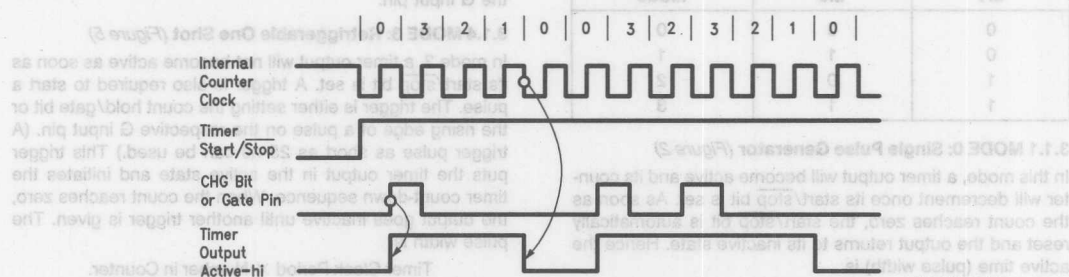

FIGURE 5. Mode 3—Retriggerable One Shot

3.2 Input and Frequency Selection

The DP8570A has a real time clock which can operate from any of four different crystal frequencies. The crystal frequency is selected in the real time mode register (Table II).

TABLE II. Real Time Mode Register
Crystal Select Bits, D7, D6

XT1	XT0	Crystal Frequency
0	0	32.768 kHz
0	1	4.194304 MHz
1	0	4.9152 MHz
1	1	32.000 kHz

This crystal frequency or a lower frequency derived from it can be used to clock the timers by programming the C2, 1, 0 bits in the timer control registers (Table III) to values 001 to 111 inclusive.

TABLE III. Timer Control Registers
Input Select Bits, D5, D4, D3

C2	C1	C0	Timer Clock
0	0	0	External
0	0	1	Crystal Frequency
0	1	0	(Crystal/Freq.)/4
0	1	1	93.5 μ s (10.7 kHz)
1	0	0	1 ms (1 kHz)
1	0	1	10 ms (100 Hz)
1	1	0	0.1 s (10 Hz)
1	1	1	1 s (1 Hz)

Alternatively, the DP8570A timers can be clocked externally via the TCK pin by writing 000 to these input clock select bits. Falling edges of a 50% duty cycle input on the TCK pin clock the timer(s) at up to 10 MHz.

The other DP8570A timer input pins are G0 and G1 for timers T0 and T1 respectively. Their action depends on the mode selected and is described above.

3.3 Output and Interrupt Selections

The T1 pin on the DP8570A is a dedicated output from timer 1, whereas the MFO pin can be configured as the timer 0 output by programming the output mode register (Table IV).

TABLE IV. Output Mode Register
Output Pin Configurations

D7	D6	MFO
0	0	INTR
0	1	T0
1	X	OSC

MFO	D7 D6	0 (For Timer/INTR Output) T0/2nd-INTR
MFO	D5 D4	Push-Pull/Open-Drain Active-Hi/Active-Lo
INTR	D3 D2	Push-Pull/Open-Drain Active-Hi/Active-Lo
T1	D1 D0	Push-Pull/Open-Drain Active-Hi/Active-Lo

already powered-up and operating correctly as a real time clock from some crystal frequency, with power supply configured and not in test mode. This example produces a 10 ms high pulse output (push-pull) every one minute using timer 1.

TABLE V. Programming Example

Write D7-0	Addr.	Reg.	Action
00000000	00000	MSR	PS = RS = 0
00000000	00010	TCR1	T1 Stopped
00000010	00000	MSR	RS = 1
0xxxxxxx	00011	ICR0	Disable T1 Intr.
00010111	10010	MSB1	} Timer
01101111	10001	LSB1	} Counter = 5999
xxxxxx10	00010	OMR	T1 = p-p, act.hi
00000000	00000	MSR	RS = 0
00101011	00010	TCR1	Start T1: Mode 1, 10 ms Input Clock

(x = Don't care in this example, but may affect other DP8570A operations.)

5.0 SYNCHRONIZATION ERRORS

As the operation of starting and stopping timers is normally asynchronous to the timer input clock, an error of up to one timer input clock period may occur. Similarly, when using the G input pins or count hold/gate bits, the following synchronization errors can occur depending on timer input clock selected:

- External (TCK) + Up to One External Clock Period.
- Crystal or Crystal/4 + Up to One Crystal Clock Period.
- Other Selections +0 to 32 μ s.

6.0 DP8571A

The DP8571A differs from the DP8570A in the following ways.

- a) It has no G0 or G1 input pins. The count hold/gate bits are fully functional however.
- b) It has no T1 timer output pin. The T1 timer read bit can be used as in the DP8570A to read the value in the timer counter and interrupts are fully functional also.
- c) The T1 bits in the output mode register (D1, 0) are RAM bits.
- d) It has no TCK input pin.
- e) An added feature of the DP8571A is it cascade mode, activated by programming T0 control register C2-0 input clock select bits to 000.

The C2-0 bits in the T1 control register are programmed to select its input clock (000 is not allowed).

6.1 DP8571A Cascade Operation

In the cascade mode, the output of timer T1 is the input clock for T0 (Figure 7). The T1 bits in the output mode register have no effect on T1 and in this mode T1 output should be considered as active-low with falling edges clocking T0.

hundreds of seconds countdown timer (with 10 ms input clock selected for T1), full range is increased from about 10.9 minutes to over 71 weeks. Also a larger variety of output waveforms can be realised by varying the values in the counters.

TABLE VI. Some Powers of 2 for Reference

Power of 2	Decimal Value
0	1
4	16
8	256
12	4,096
16	65,536
20	1,048,576
24	16,777,216
28	268,435,456
32	4,294,967,296

In cascade mode, timers cannot count down in binary from numbers greater than 65,535 if T1 contains any number other than FFFFhex. This is because T1's MSB/LSB register values are reloaded instead of FFFF when T1's count reaches 0000. The following example shows one way of working around this problem.

For countdown from 65,540 (00010004 hex) with cascaded timers:

- a) Reset Timer Control Registers.
- b) Write 00hex to T0 MSB, 01hex to T0 LSB registers and 00hex to T1 MSB, 04hex to T1 LSB registers.
- c) Setup operating conditions for timers (outputs, interrupts, etc.).
- d) Start T0 cascaded from T1, in mode 0-3 as required.
- e) Start T1 with required input, in mode 1-3 as required.
- f) After first T1 input clock (which loads T1 counter) and before the T1 count decrements to 0000hex, write FFhex to both LSB and MSB T1 registers.

The cascaded counters will continue to count down in effect as a single binary counter.

However, in modes 1 and 2, when T0 and T1 both reach 0000hex, the last values written to their LSB/MSB registers will be loaded (i.e. T0 = 0001hex, T1 = FFFFhex) unless action is taken to restore T1's original values (0004hex in this case) beforehand. One method would be for T0 to generate an interrupt on reaching 0000hex, which initiates a software routine to write the required values to T1 LSB/MSB registers before T1 decrements to 0000.

- Set the enable MSB clock bit (D2): allows the two MSB halves of the timer counters to be clocked instead of the LSB halves (LSB must be 00).
- Set signal route bits 0 and 1 (D3, 4): routes the T0 and T1 selected input clock signal (inverted) to the output and interrupt logic of the device instead of the timer outputs.

prescalers driven from an internal 32 kHz signal. If the crystal route bit is set for a timer, then its prescaler is instead driven directly by the crystal oscillator. Hence, an external signal generator faster than 32 kHz can be used to speed up testing of the timer. Real time mode register crystal select bits should be set to 32 kHz or 32.768 kHz in this case.

(Test modes are featured in detail on National Semiconductor Application Note 589.)

Typical DP8570A Interface to the IBM PC/XT for the Purpose of Engineering Evaluation

The following information has been provided to assist the reader in developing an evaluation setup for the DP8570A family of Real Time Clocks. This interface was prototyped and debugged for use in an IBM PC/XT or compatible bus computer with an accompanying program written in the C language.

Hardware Used

The interface consists of:

- DP8570A Timer Clock Peripheral
- 74ALS521 Address Decoder (I/O Hex 300 to 31F)
- 74ALS245 Transceiver (Data Bus Buffer)
- Lithium Battery (3.4V Nominal)
- Standard Pierce Parallel Resonant Crystal (32.768 kHz, ± 20 ppm)
- Various Capacitors ($\pm 10\%$)
- Various Resistors ($1/8W \pm 10\%$)

Refer to the complete schematic provided. (Figure 1)

As shown on the schematic, T1, G1, G0 MFO, INTR, and TCK are available for monitoring purposes.

Pins T1, MFO, INTR, and TCK have 3.9k pull-up resistors to V_{BB} . These resistors allow operation of T1, MFO, and INTR outputs during power down when in the battery backed mode. The resistor on TCK guarantees this input will not be floating.

National Semiconductor

Application Brief 43

Milt Schwartz

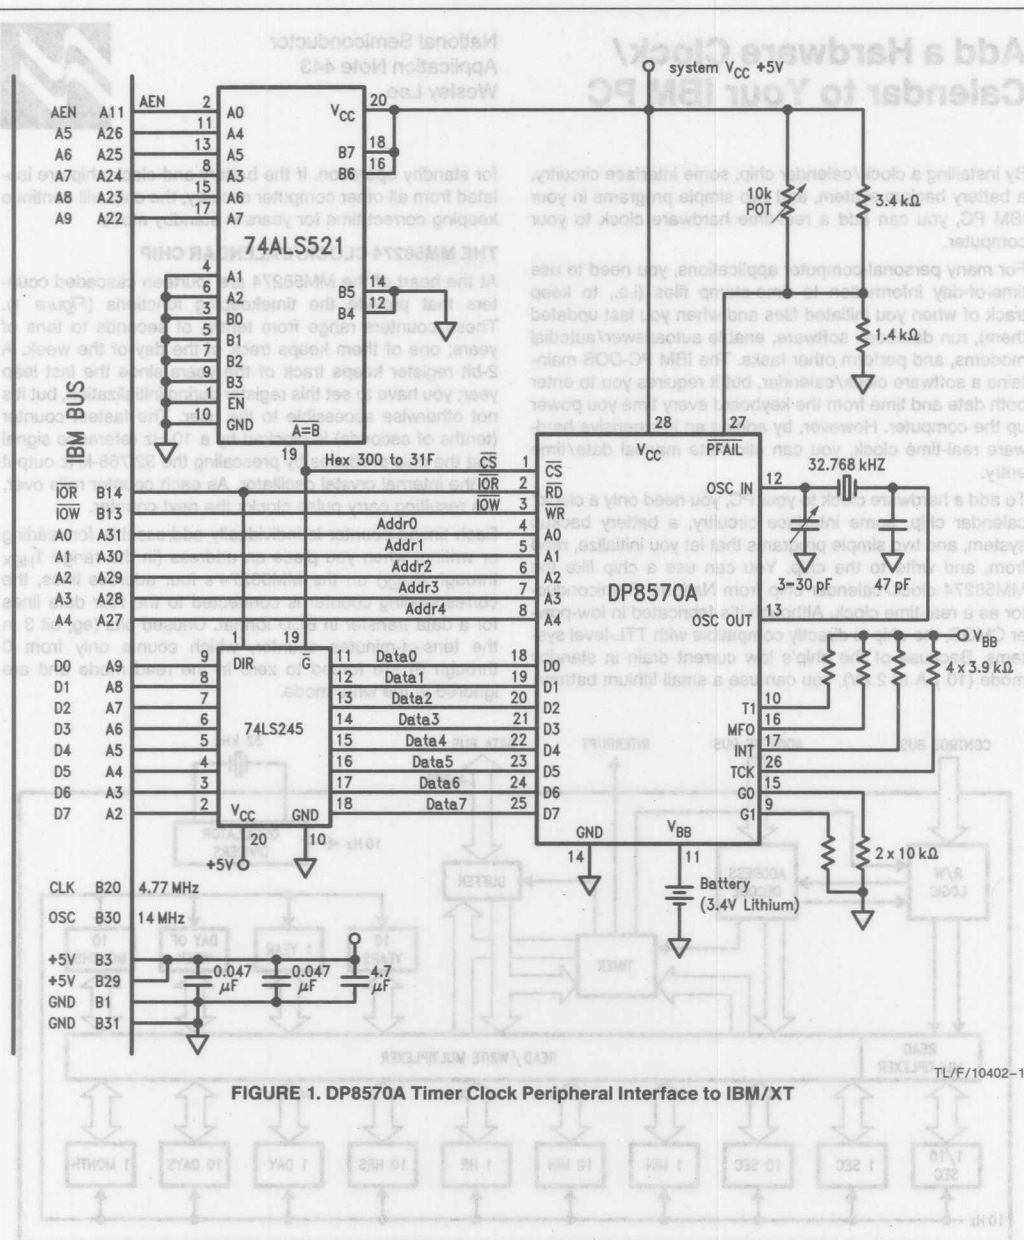

Pins G0 and G1 have 10k pull-down resistors to ground. These resistors ensure that Timer 0 and Timer 1 are enabled by the hardware.

A resistor divider was placed at the PFAIL pin in place of an external power fail signal (as suggested in the data sheet). This facilitates bus lockout during a power fail/return. The user may wish to simulate standby mode by changing the voltage at the PFAIL pin. For example, this may be accomplished by connecting a resistor (fixed or variable) in parallel with the 3.4k resistor.

Separate power supplies for V_{CC} and V_{BB} may be used in place of the system 5V supply and battery for the purpose of monitoring the supply currents.

Software

A demo program, TCP, was written in C language and designed to run on MS-DOS or PC-DOS. The program TCP consists of several pop up menus with the initial display as the main menu. This menu lists the available functions which may be called. Each pop up menu prompts for an entry and provides on-screen documentation.

By installing a clock/calendar chip, some interface circuitry, a battery backup system, and two simple programs in your IBM PC, you can add a real-time hardware clock to your computer.

For many personal-computer applications, you need to use time-of-day information to time-stamp files (i.e., to keep track of when you initiated files and when you last updated them), run datebook software, enable autoanswer/autodial modems, and perform other tasks. The IBM PC-DOS maintains a software clock/calendar, but it requires you to enter both date and time from the keyboard every time you power up the computer. However, by adding an inexpensive hardware real-time clock, you can eliminate manual date/time entry.

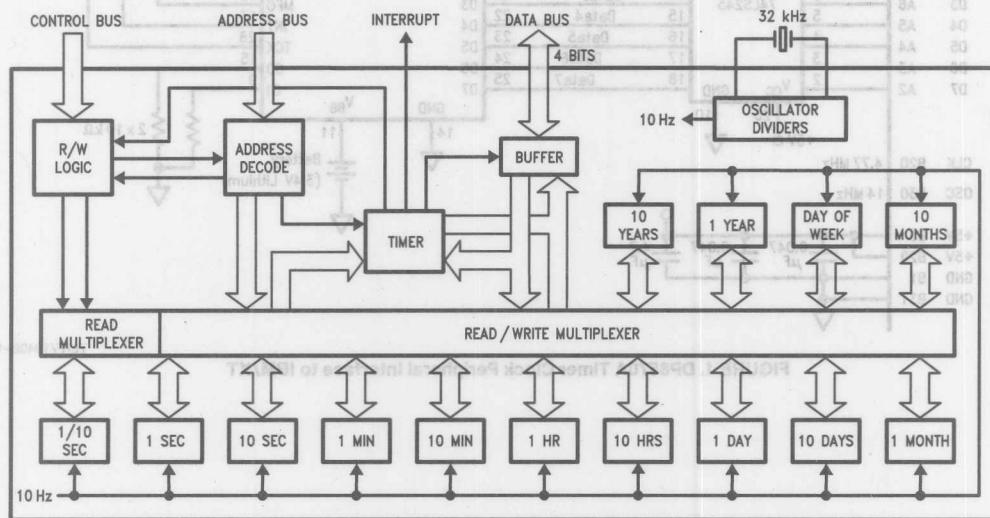

To add a hardware clock to your PC, you need only a clock/calendar chip, some interface circuitry, a battery backup system, and two simple programs that let you initialize, read from, and write to the chip. You can use a chip like the MM58274 clock/calendar chip from National Semiconductor as a real-time clock. Although it's fabricated in low-power CMOS, the chip is directly compatible with TTL-level systems. Because of the chip's low current drain in standby mode (10 μ A at 2.2V), you can use a small lithium battery

for standby operation. If the battery and clock chip are isolated from all other computer circuitry, the chip will continue keeping correct time for years in standby mode.

THE MM58274 CLOCK/CALENDAR CHIP

At the heart of the MM58274 are fourteen cascaded counters that provide the timekeeping functions (Figure 1). These counters range from tenths of seconds to tens of years; one of them keeps track of the day of the week. A 2-bit register keeps track of the years since the last leap year; you have to set this register during initialization, but it's not otherwise accessible to the user. The fastest counter (tenths of seconds) is clocked by a 10-Hz reference signal that the chip produces by prescaling the 32,768-kHz output of the internal crystal oscillator. As each counter rolls over, the resulting carry pulse clocks the next counter.

Each timing counter is individually addressable for reading or writing; when you place an address (in the range 1_{HEX} through E_{HEX}) on the MM58274's four address lines, the corresponding counter is connected to the four data lines for a data transfer in BCD format. Unused bits (eg, bit 3 in the tens-of-minutes counter, which counts only from 0 through 5) are forced to zero in the read mode and are ignored in the write mode.

TL/F/8690-1

FIGURE 1. Although it's fabricated in low-power CMOS, the MM58274 clock/calendar chip is directly compatible with TTL-level systems. It includes 14 cascaded counters that provide the timekeeping functions.

Note that the timing counters account for only 14 of the chip's 16 addresses. The remaining two—0_{HEX} and F_{HEX}—are described in Figures 2 and 3, respectively. Address 0_{HEX} operates as a control register when written to and as a status register when read from; address F_{HEX} is the clock-setting or interrupt register, depending on the state of bit DB₂ in the control register. (Note that the 16 MM58274 addresses can be offset from the IBM PC's 0_{HEX} I/O address space. The chip might occupy locations 300_{HEX} to 30F_{HEX} in the computer's I/O space, for example, as Table I shows.)

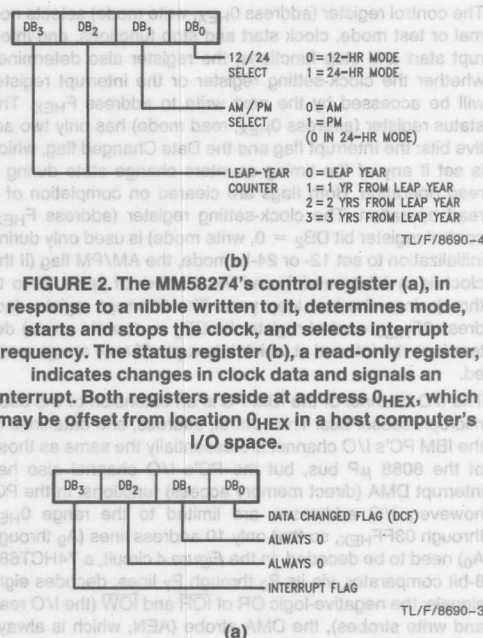

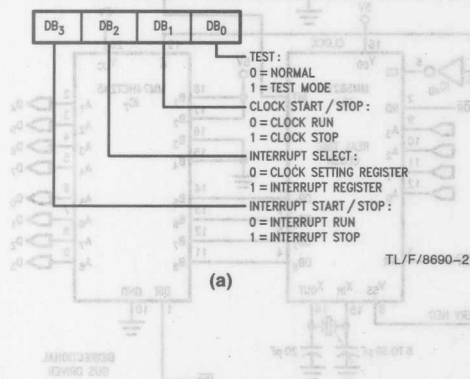

FIGURE 2. The MM58274's control register (a), in response to a nibble written to it, determines mode, starts and stops the clock, and selects interrupt frequency. The status register (b), a read-only register, indicates changes in clock data and signals an interrupt. Both registers reside at address 0_{HEX}, which may be offset from location 0_{HEX} in a host computer's I/O space.

DB ₃	DB ₂	DB ₁	DB ₀	FUNCTION	COMMENTS
X	0	0	0	NO INTERRUPT	INTERRUPT OUTPUT CLEARED
0/1	0	0	1	0.1 SEC	START/STOP BIT SET TO 1
0/1	0	1	0	0.5 SEC	DB ₃ = 0, SINGLE INTERRUPT
0/1	0	1	1	1 SEC	DB ₃ = 1, PERIODIC INTERRUPT
0/1	1	0	0	5 SEC	
0/1	1	0	1	10 SEC	
0/1	1	1	0	30 SEC	
0/1	1	1	1	60 SEC	

TL/F/8690-5

FIGURE 3. The state of bit DB₂ in the control register at address 0_{HEX} selects one of two command registers at address F_{HEX}. If the control register's DB₂ equals 0, then F_{HEX} becomes the clock-setting register (a). If DB₂ is 1, then F_{HEX} becomes the interrupt register (b).

The control register (address 0_{HEX}, write mode) selects normal or test mode, clock start and stop functions, and interrupt start and stop functions; the register also determines whether the clock-setting register or the interrupt register will be accessed by the next write to address F_{HEX}. The status register (address 0_{HEX}, read mode) has only two active bits: the Interrupt flag and the Data Changed flag, which is set if any of the timing counters change state during a read operation. Both flags are cleared on completion of a read operation. The clock-setting register (address F_{HEX}, control register bit DB₂ = 0, write mode) is used only during initialization to set 12- or 24-hr mode, the AM/PM flag (if the clock is in 12-hr mode), and the number of years (zero to three) since the last leap year. The interrupt register (address 0F_{HEX}, control register bit DB₂ = 1, write mode) determines the interval at which interrupts (if any) are generated.

The I/O channel of the IBM PC is an extension of the 8088 microprocessor bus. The control, address, and data lines of the IBM PC's I/O channel are essentially the same as those of the 8088 μ P bus, but the PC's I/O channel also has interrupt DMA (direct memory access) functions. In the PC, however, I/O addresses are limited to the range 0_{HEX} through 03FF_{HEX}, so that only 10 address lines (A₉ through A₀) need to be decoded. In the Figure 4 circuit, a 74HCT688 8-bit comparator, via its P₀ through P₇ lines, decodes eight signals: the negative-logic OR of I_{OR} and I_{OW} (the I/O read and write strobes), the DMA strobe (AEN, which is always

low for an I/O operation), and the upper six address bits (A₉ through A₄). The base address of the MM58274 is set by the six DIP switches connected to the corresponding Q inputs of the comparator. Address lines A₃ through A₀ are connected directly to the MM58274 address inputs.

The 74HCT688 compares the eight P and Q inputs for equality. When a P = Q condition becomes true, the comparator generates an active-low device-enable strobe (DEN). This signal enables the MM58274, a MM74HCT164 (a wait-state generator), and a 74HCT245 bidirectional bus driver connecting the clock data lines to the IBM bus. Pullup and pulldown resistors on the bus driver force the upper nibble of the IBM bus to 3_{HEX} during an I/O read operation, thus adding 30_{HEX} to the BCD output of the clock to convert the BCD number to the corresponding ASCII character.

You don't need to use DIP switches to change the base address of the MM58274 (you could, for instance hard-wire the address), but it's standard practice to include DIP switches on I/O interface cards that are added to any microcomputer. Take care not to assign the same I/O address or addresses to more than one device; if you do, I/O devices will contend for the bus, with unpredictable results. Table 1 shows the standard I/O addresses recognized by PC-DOS version 2 as well as the address space used by the MM58274 (300_{HEX} to 30F_{HEX}) and, incidentally, by the popular AST Super-Pack card. If you have any other add-in cards in your system, be sure to check the documentation

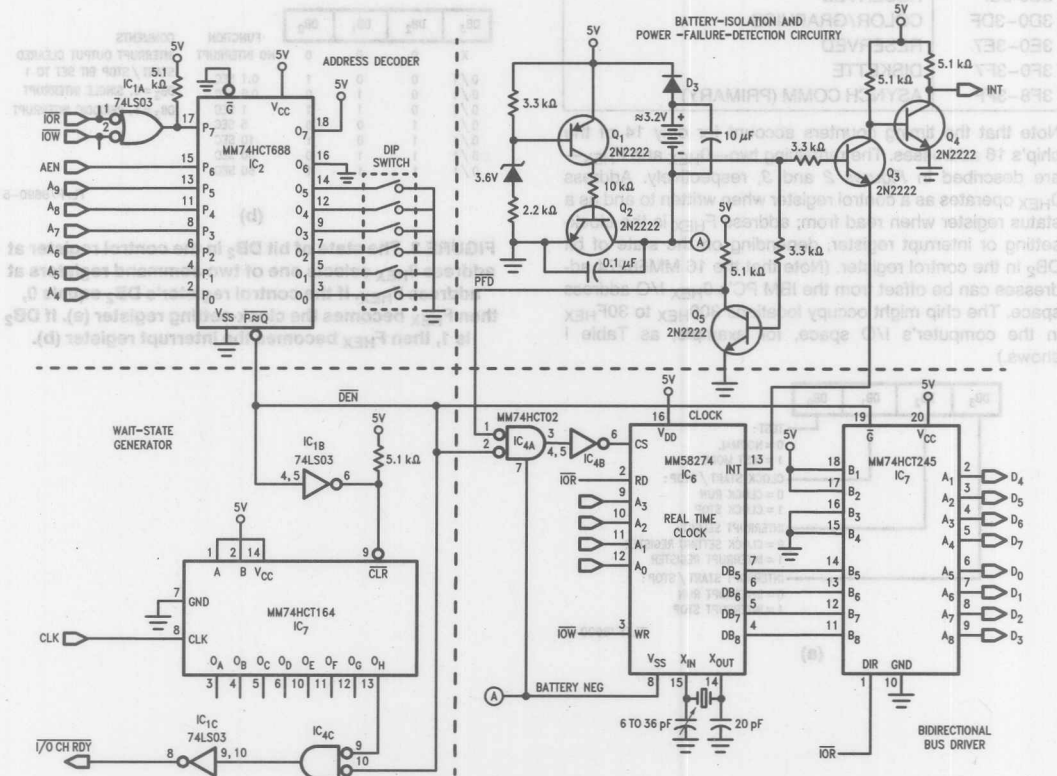

FIGURE 4. The MM58274 requires relatively few support chips: Adding a bidirectional bus driver, a wait-state generator, and an address decoder lets you implement all essential functions of the MM58274.

TL/F/6690-6

to determine which addresses they use, so you can avoid I/O address duplication.

ISOLATION PROLONGS BATTERY LIFE

The battery-isolation circuits in *Figure 4* prevent reverse current from flowing through the battery when the main power supply is on, and they minimize current drain in the battery backup mode. Diode D_3 (*Figure 4*) isolates the battery during system power-up. As long as the system power supply is at least one diode drop (0.6V) above the battery voltage ($\sim 3V$), diode D_3 is reverse-biased, and no current can flow into or out of the battery. If the supply voltage drops below this level, the battery powers the clock.

To prolong battery life in standby mode, you should eliminate all leakage paths to ground. Don't insert a switch in the +5V bus, though; that alone would be ineffective, as *Figure 5* shows. A ground-disconnect switch (Q_2 in *Figures 4* and *5*) eliminates leakage from the RD, WR, and CS pins through the protection diodes. However, even when the ground-disconnect switch is open, a leakage path still exists through the INT pin and an open-drain transistor to ground; thus, a second switch (Q_3) is needed to open this path also.

When the system powers down, transistor Q_1 shuts off, thereby also shutting off Q_2 (the ground-disconnect switch), Q_3 (the interrupt-disconnect switch), and Q_5 (the power-failure detector). Shutting off these transistors not only isolates the negative terminal of the battery from the system ground bus but also breaks the leakage paths indicated in *Figure 5*.

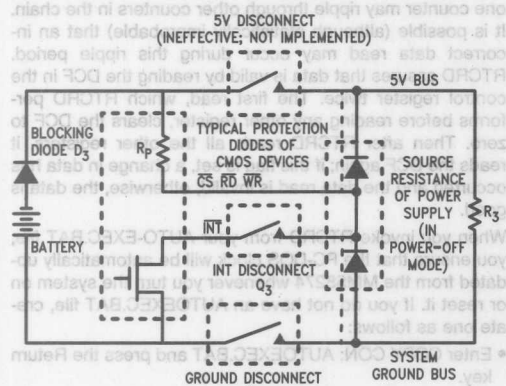

FIGURE 5. To prevent leakage from the battery via CS, RD, WR, and INT, you must break the INT path and disconnect battery negative from system ground. A switch in the +5V lead wouldn't break the leakage paths and thus isn't implemented.

When Q_5 shuts off, the power-failure circuitry disables the clock chip by forcing the \overline{CS} (chip select) signal high. The \overline{CS} signal is the negative-logic AND of DEN (the device-enable signal) and \overline{PFD} , both of which are active-low. If either one goes high (because the clock is not being addressed, or because system power is low or off), the two sections (IC_{4A} and IC_{4B} in *Figure 4*) of the 74HCT02 drive the \overline{CS} input high to disable the clock chip.

TIMING CONSIDERATIONS

Your interface circuitry will have to compensate for some incompatibility between the PC and the MM58274. The IBM PC requires that data be read from a device in three clock cycles (630 ns). However, the read-access time of the MM58274 is 850 ns. To slow down the computer, you need a wait-state signal that pulls the I/O CH RDY bus line low for one or more clock cycles. The wait-state generator (*Figure 4*) consists of an MM74HCT164 shift register, a negative-logic AND gate (IC_{4C} , one section of a 74HCT02 NOR chip), and an open-collector inverter (IC_{1C} , one section of a 74LS03). Until the clock is addressed, \overline{DEN} remains high, clearing the shift register via inverter IC_{1B} ; at this time the Q_H output of the shift register is low. When the clock is addressed, \overline{DEN} goes low, removing the CLR signal from the shift register and enabling the second input of IC_{4C} so that I/O CH RDY goes low and puts the microprocessor into a wait state. Subsequent clock pulses gradually fill the shift register with ones, starting from the left. The number of wait states generated depends on which output of the shift register you use. This application uses the last tap, so that the microprocessor is delayed for eight clock pulses (8×210 ns). The delay allows plenty of time for MM58274 read and write operations to take place. When the Q_H output goes high, I/O CH RDY also goes high to terminate the wait state.

Another incompatibility between the IBM PC and the MM58274 occurs in the write-cycle specification, t_{WD} (Data Bus Hold Time Following Write strobe). The MM58274 requires the system to hold data for 200 ns after the end of the write strobe, whereas the IBM PC holds data on the bus for only 100 ns. However, by disabling the bus driver immediately after writing data to the MM58274, the 3-state capacitance (typically 25 pF) of the bus driver maintains the data on the clock lines for a period of time after the end of the write strobe. When this technique was used experimentally, the typical measured values of the Data Bus Hold Time ranged from 500 to 600 ns.

The time-base reference of the MM58274 is a 32.768-KHz pulse obtained from a crystal-controlled internal oscillator. One side of the crystal is loaded with a 20-pF fixed capacitor and the other side with a 6- to 36-pF trimmer capacitor (*Figure 4*). For accurate timekeeping (within 30 sec/month), you must adjust this trimmer capacitor so that the crystal oscillates at the correct frequency. You shouldn't connect measuring instruments directly across the crystal, because

buffered signal for an oscilloscope or frequency counter.

PROGRAM THE MM58274 TO PRODUCE INTERRUPTS

You can program the clock chip to produce a single interrupt or repetitive interrupts at any one of seven intervals from 0.1 to 60 sec by loading the interrupt register (Figure 3). To make use of interrupts, connect the INT output from transistor Q₅ (Figure 4) to one of the IRQ lines of the IBM PC bus. Six of the eight interrupt levels are reserved for IBM devices; only IRQ₃ and IRQ₅ are available for use with the clock. If you have other add-in cards that use interrupts, however, IRQ₃ and IRQ₅ may be pre-empted, so you won't be able to use interrupts.

To integrate the hardware clock/calendar into your system, you use two 8088 assembly-language programs (the source listings are coded for DOS 2.0). The first, RTCWR (see Listing 1) allows you to put the MM58274 either in test mode to calibrate the crystal clock or in normal mode to initialize time and date. The other routine, RTCRD (see Listing 2) reads the clock, displays the date and time in the upper right corner of the screen, and writes the date and time into the software clock that PC-DOS maintains. Thus, if your AUTOEXEC.BAT file invokes RTCRD, the routine automatically updates the PC-DOS clock from the hardware clock whenever you turn on the system.

Incidentally, RTCWR and RTCRD don't contain routines to perform keyboard input and screen output; they use standard function calls to DOS and BIOS routines (of which a complete listing is given in the *IBM PC Technical Reference Manual*) to perform these functions. Placing a function code in the AH register and executing the appropriate software-interrupt instruction invokes these routines. The *PC DOS Programmer's Manual* gives full details on how to make service requests of this kind.

After assembling and linking the RTCWR.ASM and RTCRD.ASM programs, copy the resulting RT-CWR.EXE and RTCRD.EXE files to your system disk. To calibrate the crystal oscillator, connect an oscilloscope or frequency counter between pin 13 of the MM58274 and ground. At the A> prompt, type the following command:

```
RTCWR/C<Return>
```

The C option puts the clock in the test mode, diverting the 32.768-kHz oscillator output through a buffer to pin 13 of the chip. Adjust the trimmer capacitor until the frequency is correct. Then type "S" to exit from the calibration mode to the time-setting mode. RTCWR will prompt you to select 12- or

and you exit to PC-DOS. The next time you wish to initialize the hardware, invoke RTCWR *without* the C option, unless you wish to recalibrate the oscillator.

To read the real-time clock, run the program RTCRD.EXE. In short, the program reads the date, places it in a temporary buffer, and displays it. It then reads and displays the time in the same manner. All data reads are validated by means of the Data Changed flag. The program also writes the date and time into the PC-DOS software clock.

RTCRD calls the BIOS display by using the following instruction sequence:

```
MOV AH, 2  
MOV BH, 0  
MOV DH, ROW  
MOV DL, COL  
INT 10H
```

This call displays the day, date, and time in the upper right corner of the screen. You can change the location of the display by changing the values for row and column (ROW and COL).

Date and time information needs to be validated by means of the Data Changed flag (DCF), because a carry pulse from one counter may ripple through other counters in the chain. It is possible (although statistically improbable) that an incorrect data read may occur during this ripple period. RTCRD assures that data is valid by reading the DCF in the control register twice. The first read, which RTCRD performs before reading any other register, clears the DCF to zero. Then after RTCRD reads all the other registers, it reads the DCF again; if this flag is set, a change in data has occurred and the data read is invalid; otherwise, the data is good.

When you invoke RTCRD from your AUTO-EXEC.BAT file, you ensure that the PC-DOS clock will be automatically updated from the MM58274 whenever you turn the system on or reset it. If you do not have an AUTOEXEC.BAT file, create one as follows:

- Enter COPY CON: AUTOEXEC.BAT and press the Return key.
- Enter RTCRD and press the Return key.
- Press the F6 function key and then the Return key to write an end-of-file mark and save the new AUTOEXEC.BAT file.

If you already have an AUTOEXEC.BAT file, use your normal editor to insert "RTCRD" as the first line in the file.

Clocks with the Battery Backed Mode Selected

This application note describes how external oscillators may be used with the DP857x family of real time clocks, by using the "test mode" to configure the DP857x in the battery backed mode prior to starting the clock.

THE PROBLEM

In the battery backed mode, the external oscillator peak-to-peak voltage must not exceed the voltage at the V_{BB} pin. When the chip is first time powered up, it is in the single supply mode. The single supply mode references the oscillator inverter to V_{CC} . This means that in normal operation the OSC in pin needs to swing positively to about 3.5V minimum. If an external oscillator is set to the V_{BB} value, then its high going signal may not be high enough to trip the internal inverter. If the internal inverter doesn't pass the external signal, you cannot program the chip into the battery backed mode, because the internal OSC fail signal will always be set (catch-22).

THE SOLUTION

General Description

Select the test mode and disable the oscillator fail circuitry (refer to AN 589 in the Real Time Clock Handbook). Now, the battery backed mode may be selected independent of

any oscillator signal. This action references the internal inverter to V_{BB} . As a result, the inverter will pass the external oscillator signal which is set to the battery voltage plus one diode drop. Once the chip is operating in the battery backed mode, clear the "test mode" register and leave the test mode. The circuits of Figures 1 and 2 were used to check out this solution. Both the LP2951 and LM611 are available as mini-dip packages. The LP2951 is more expensive, but is designed to do this type of application and is fully compensated for temperature and voltage changes. As shown, the circuits provide for battery backed operation of the external oscillator and DP857x. The disadvantage is extra current drain from the battery. The advantage is that the user has complete control over the oscillator design and can temperature compensate as well as tune the oscillator for maximum accuracy. The external oscillator was implemented using a 74HC04 (see Figures 3 and 4). The 74HC device was chosen because it is specified to operate down to 2.0V. A commercial oscillator could be used as long as it can operate at the V_{BB} voltage chosen by the user. Figure 5 is a set of curves of C_{OUT} versus C_{IN} for a 32.768 kHz Pierce parallel resonant oscillator. These curves are helpful for choosing starting values for the oscillator to ensure reliable start up and nominal operation.

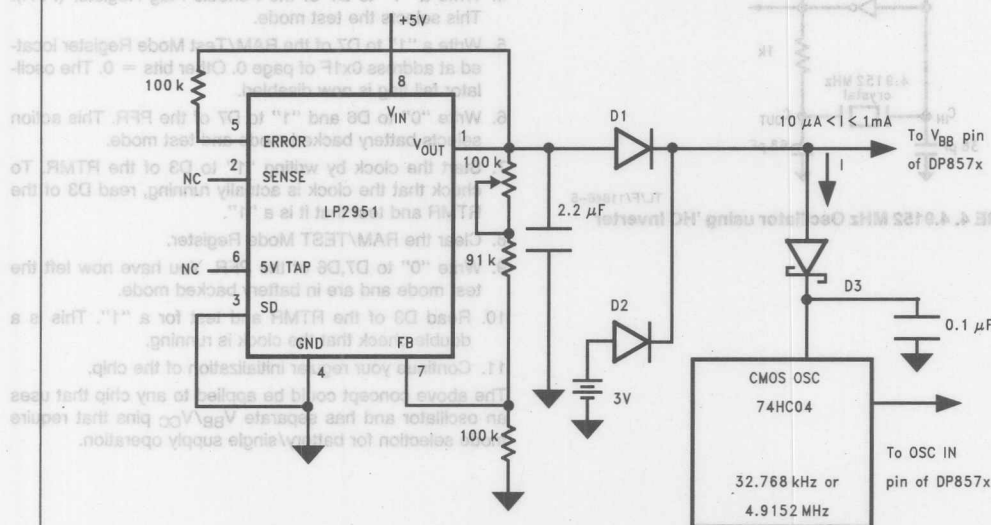

FIGURE 1. Voltage Regulator as a V_{CC} Supply for an External Oscillator

TL/F/11846-1

FIGURE 2. LM611 as a VCC Supply for an External Oscillator

DETAILED DESCRIPTION

Initialization procedure for first time power on:

1. Adjust output of voltage regulator to be 0.25V higher than V_{BB} . This will make sure that D2 is reversed biased and the battery will not power the external oscillator when V_{CC} is powered. For this case D1 and D2 are the same diodes (1N914). An alternate method is to use a Schottky diode for D1 and a 1N914 for D2. Then adjust the output of the voltage regulator equal to the battery. D3 is a Schottky diode (1N6263) that ensures the high level output of the oscillator is slightly lower than V_{BB} .
2. Connect external oscillator to OSC IN pin, and leave OSC OUT unconnected.
3. Select the clock frequency by writing to bits D6,D7 of the Real Time Mode Register (RTMR).
4. Write a "1" to D7 of the Periodic Flag Register (PFR). This selects the test mode.
5. Write a "1" to D7 of the RAM/Test Mode Register located at address 0x1F of page 0. Other bits = 0. The oscillator fail flag is now disabled.
6. Write "0" to D6 and "1" to D7 of the PFR. This action selects battery backed mode and test mode.
7. Start the clock by writing "1" to D3 of the RTMR. To check that the clock is actually running, read D3 of the RTMR and test that it is a "1".
8. Clear the RAM/TEST Mode Register.
9. Write "0" to D7,D6 of the PFR. You have now left the test mode and are in battery backed mode.
10. Read D3 of the RTMR and test for a "1". This is a double check that the clock is running.
11. Continue your regular initialization of the chip.

The above concept could be applied to any chip that uses an oscillator and has separate V_{BB}/V_{CC} pins that require mode selection for battery/single supply operation.

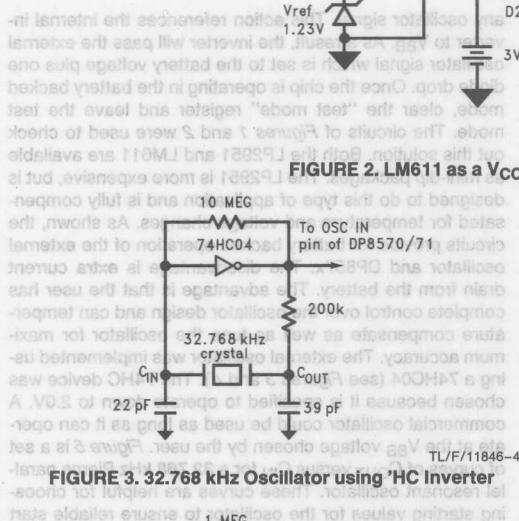

FIGURE 3. 32.768 kHz Oscillator using 'HC Inverter

FIGURE 4. 4.9152 MHz Oscillator using 'HC Inverter

32.768 kHz Oscillator Hints for a Pierce Parallel Resonant Circuit

The below curves are a plot of C_{OUT} versus C_{IN} for constant Load Capacitance (C_L). The load capacitances selected show the typical range specified by various manufacturers.

The expression for calculating C_L is $\frac{1}{C_L} = \frac{1}{C_{IN}} + \frac{1}{C_{OUT}}$

Where C_{OUT} is usually greater than C_{IN}

Refer to AN-588 for additional information.

FIGURE 5

DP8570A Experiments to Test the Low Battery Bit or Generate a Periodic Interrupt

National Semiconductor
Application Note 894
Milt Schwartz

SUMMARY

This application note describes two experiments. One experiment allows the user to check that the low battery bit is working correctly. The other allows the user to generate a 10 ms periodic interrupt.

A program named RTC, written in Microsoft™ Quick C version 1, is used for both experiments. The code works with the circuit shown in *Figure 3*. This circuit is a general purpose interface for use with an IBM® PC-XT® or PC-AT® (or equivalent). Keyboard entries may be either upper or lower case, but the underscores must be included.

Type `rtc` to execute the program, then follow the instructions on the monitor.

LOW BATTERY BIT EXPERIMENT

Equipment: Variable lab supply or 20k pot, center tapped to the V_{BB} pin.

An oscilloscope with 10 M Ω , 10 pF probe or higher impedance.

The initial screen output is shown in Message 1. Before selecting the `LOW_BATT_BIT` mode, set the voltage at the V_{BB} pin to about 2.5V. If V_{BB} is GND or too low a voltage, a message should appear (see Message 2). Once the `LOW_BATT_BIT` mode is running, you should see screen output (see Message 3). The status of the low battery bit is displayed in the lower left of the monitor. A value of 0 indicates V_{BB} is higher than the internal threshold detector. A value of 40 indicates the low battery bit is set.

Monitor the waveform at the OSC OUT pin. Observing the peak-to-peak voltage of this waveform is the only way to know that the DP8570A is in the battery backed mode, unless the test mode is selected. The waveform is sinusoidal in form and swings within 0.6V of V_{BB} and ground. Refer to *Figures 1a, 1b, 1c*.

Vary the V_{BB} voltage slowly as you approach 2.3V. If the V_{BB} voltage gets too low (less than 1.8V) the oscillator may stop. During the low battery bit mode, if V_{BB} is grounded or a too low a voltage, you will not get any indication on screen. If you hit the spacebar and re-enter the `LOW_BATT_BIT` mode, Message 1 warning will appear on the monitor.

10 ms INTERRUPT EXPERIMENT

Equipment: An oscilloscope is needed to monitor the INTR pin.

Before starting this section of the program, connect V_{BB} to ground. The `INTR_10 ms` code configures the DP8570A in the Single Supply mode. Message 4 is output to the monitor indicating you are in the 10 ms Interrupt mode. *Figure 2a* shows expected waveforms for a PC-XT (4.77 MHz); *Figure 2b* a 386/33 MHz AT.

```

                                Check that the Oscillator has started.
                                If you don't get osc running in 5 seconds, the program will abort

                                The Oscillator is running. The Clock is started.

You may choose the  'Low Battery Bit' Test    or
                   'the 10ms Interrupt' Test or
                   'END to return to DOS'

Type in your choice in the following format, then hit ENTER:

Choices are:        LOW_BATT_BIT  or
                   INTR_10ms     or
                   END    to exit the Program

Enter your choice now:
  
```

Message 1: Initial Screen Display (Normal Operation)

Watch out! VBB is at Ground or some illegal value

VBB voltage should be between 2.2V and VCC - 0.4V

Message 2: VBB Warning

FIGURE 1d

Battery backed mode selected.

Check waveform at osc out to see if referenced to the battery voltage

Peak value should be less than the battery voltage

V_{BB} = 5V

Adjust voltage on VBB pin while monitoring screen.

The bottom left side of the screen will display zero

if VBB > threshold (about 2.1 volts),

or 40 if VBB < threshold.

This test may be ended by hitting the space bar.

AN-895

THE PROBLEM

THE SOLUTION

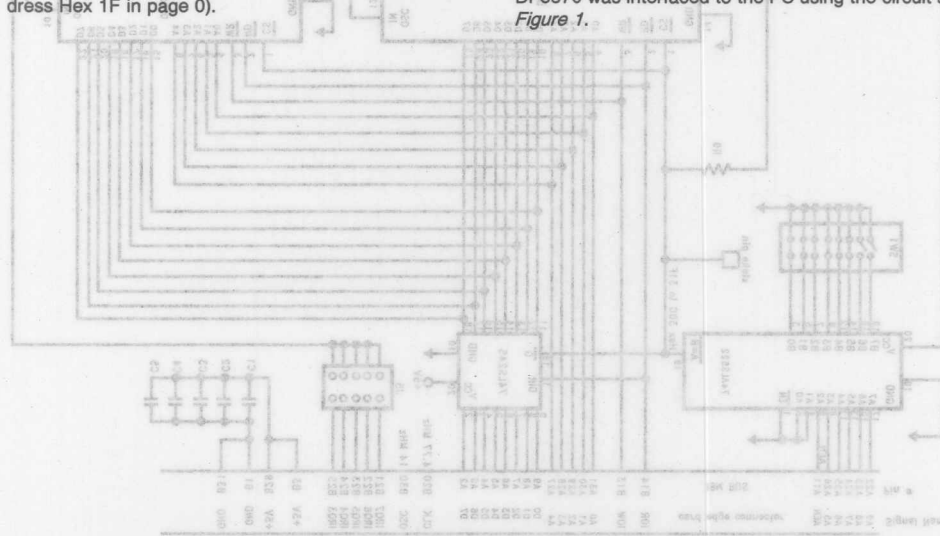

1. Write a '1' to bit D7 of the Periodic Flag Register (PFR). Now you are in the Test Mode.
2. Write '1' to bit D7 of the Test Register (address Hex 1F in page 0), all other bits are '0'. This action disables the OSC FAIL bit.
3. Write a '1' to bit D6 of the PFR. This action changes the RTC from battery backed mode to single supply mode.
4. Now the battery can be changed. If the change takes place within a half minute or so, the V_{BB} pin can be left floating for that time. If the battery is soldered in such that many minutes will occur, then temporarily connect V_{BB} to ground until the new battery is ready for installation.
5. After the battery is connected, to return to battery backed mode:

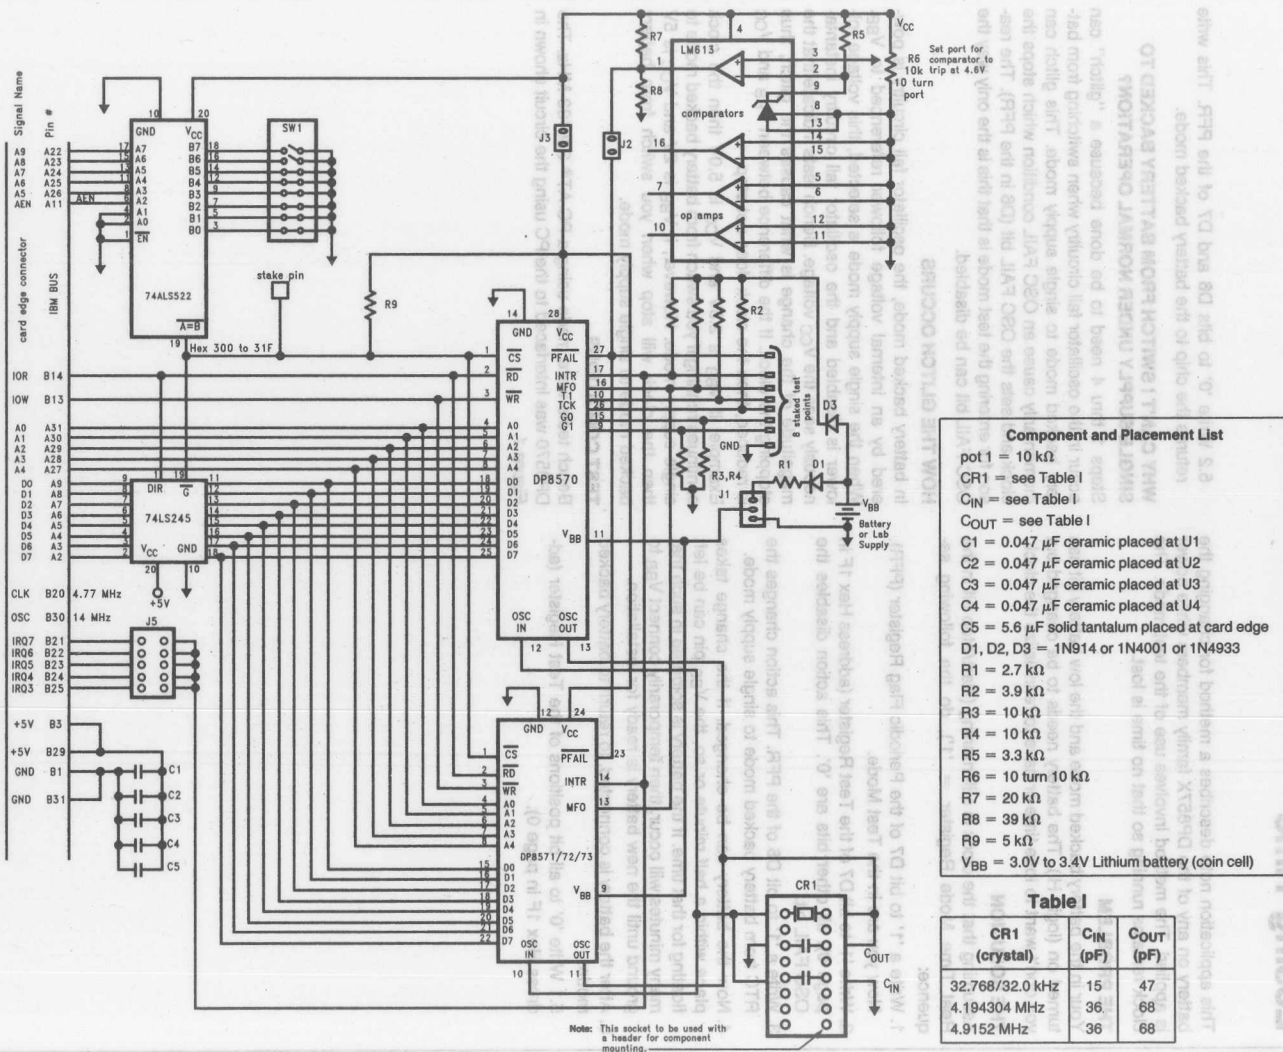

WHY CAN'T I SWITCH FROM BATTERY BACKED TO SINGLE SUPPLY UNDER NORMAL OPERATION?

HOW THE GLITCH OCCURS

Example: If V_{BB} is 2.5V and V_{CC} is 5.0V then the clock continues running if you switch from battery backed mode to single supply mode. However, if V_{BB} is 2V and V_{CC} is 5V then the clock will stop when you switch from battery backed mode to single supply mode.

Bench tests were made using a PC-AT® 386/33 MHz. The DP8570 was interfaced to the PC using the circuit shown in *Figure 1*.

Ceramic Sidebrazed Dual-in-Line Package
Package Number D24C

Technical drawing showing the top and side views of the Ceramic Sidebrazed Dual-in-Line Package (D24C). The top view shows a rectangular package with 24 pins (13 on each long side) and dimensions: 1.230 (31.24) MAX for the width and 0.568-0.605 (14.43-15.37) for the height. The side view shows the package height and the side braze. The drawing includes various dimension lines and labels for pin numbers and package features.

Ceramic Dual-in-Line Package

Package Number J16A

Technical drawing of a Ceramic Dual-in-Line Package (J16A) showing dimensions in inches and millimeters.

Top View Dimensions:

- Overall width: 0.785 (19.939) MAX
- Pin pitch (top): 0.025 (0.635) RAD
- Pin pitch (bottom): $0.220 - 0.310$ (5.588 - 7.874)
- Pin 1 indicator: $0.005 - 0.020$ (0.127 - 0.508) RAD TYP

Side View Dimensions:

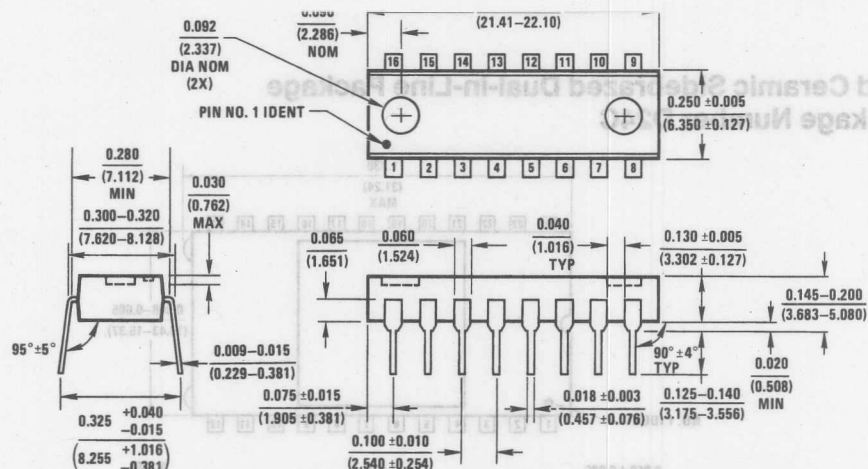

- Package height: $0.290 - 0.320$ (7.366 - 8.128)
- Lead height: 0.180 (4.572) MAX
- Lead angle: $95^\circ \pm 5^\circ$
- Lead thickness: $0.008 - 0.012$ (0.203 - 0.305)
- Lead spacing: 0.005 (0.127) MIN

End View Dimensions:

- Package thickness: 0.080 (2.032) MAX BOTH ENDS
- Pin thickness: 0.055 ± 0.005 (1.397 \pm 0.127)
- Pin pitch (end): 0.018 ± 0.003 (0.457 \pm 0.076)
- Pin thickness (end): 0.100 ± 0.010 (2.540 \pm 0.254)
- Pin spacing (end): $0.125 - 0.200$ (3.175 - 5.080)
- Pin spacing (end): $0.020 - 0.060$ (0.508 - 1.524)
- Pin thickness (end): 0.037 ± 0.005 (0.940 \pm 0.127)
- Pin spacing (end): 0.150 (3.810) MIN
- Pin angle: $86^\circ 94'$ TYP
